## Comparison of topsoil developing features of commonly used hydraulic biotic soil amendments

| | Organix™ | Proganics™ Biotic Soil Media™ | Biotic Earth™ | Topsoil | PermaMatrix® | Compost | Fusion™ |
|---|---|---|---|---|---|---|---|
| **Beneficial Microbes** – Essential for a soil to remain alive and vital. Improves nitrogen fixation, soil structure, and maintenance of nutrients. | ○ | | | ● | ● | ● | ● |
| **Microbial and Plant Growth Stimulators** – Improves plant cell division, photosynthesis, and nutrient use which creates healthy and robust plants. | ○ | ● | ● | ● | ● | ● | ● |
| **Peat** – Increases water retention of soil and releases humic and fulvic acid. Well known stable growth medium. | ○ | | ● | | | | ● |
| **U.S. Compositing Council Certified Compost** – A growth medium for nutrient maintenance. Food source for microbes. Helps to build soil structure/aggregates. Releases humic and fulvic acids, other essential amino acids and vitamins. | ○ | | | | | ● | ● |
| **Mycorrhizae** – Creates healthier and more robust plants through improved root development. | ○ | ● | ● | | ● | | ● |
| **Thermally Processed Wheat Straw** – Efficient soil cover regulating heat and moisture at the surface. Provides carbon, organic material and a microbial energy source that easily degrades. Does not lock up nutrients (like wood fibers.) | ○ | | ● | | | | ● |
| **Long-term Interlocking Fiber** – Holds all other fibers together and provides microbial energy source for up to 2 years. | ○ | ● | ● | | | | ● |
| **Organic Hydrocolloidal Tackifier** – Provides initial energy source for microbes while sticking all materials together and to the soil. | ○ | ● | | | | | ● |
| **Chemistry For Soil Structure** – Rapidly develops and preserves existing soil structure and pore space which allows for proper infiltration while reducing soil crusting and soil loss. | ○ | | | | | | ● |
| **Erosion Control** – NO additional erosion control treatment needed. | | | | | | | ● |

**Upgrade to Fusion™ for a one step HBSA offering soil replacement or soil building AND erosion control.**

# Plant Table

| | Ref # | Common Name | Botanical Name | Goes Well With (Ref #) | Max Height 100cm = 1m = 3.3ft | Soil: **D**ry · **M**oist · **W**ell Drained | Light: **Sh**ade · **Su**n · **P**artial Sun | Bloom Period | Characteristics | Plant descriptions, suggested uses, and additional species |
|---|---|---|---|---|---|---|---|---|---|---|
| TREES | 1 | Garry Oak | *Quercus garryana* | 2, 3, 6, 14 | 15 - 30m | D, M, WD | S, PS | n/a | | Slow-growing, can be a large tree or shrubby bush, leathery dark glossy leaves, acorns attract many species |
| | 2 | Arbutus | *Arbutus menziesii* | 1, 3, 29, 32 | 15 - 20m | D, WD | S, PS | Apr-May | | Fragrant showy white flower clusters, red berries, beautiful red and green peeling bark on smooth, curvy branches |
| | 3 | Shore Pine | *Pinus contorta* | 1, 2, 26, 29, 32 | 10 - 15m | D, WD | S | n/a | | A seaside favorite! Handles salt, wind & poor soil, grows straight in average soil, bonzai in poor, acid soil |
| | 4 | Pacific Willow | *Salix lucida* | 15, 17, 20, 24 | 6 - 15m | M | S | Apr-May | | Create thickets near water, shade out weeds, and grow from cuttings. Also try: *S. scouleriana, S. hookeriana* |
| | 5 | Vine Maple | *Acer circinatum* | 11, 16, 22, 38 | 3 - 7m | D, M | Sh, S, PS | Apr | | Red flowers in spring, red leaves in autumn, resprouts from roots. Forms tree in open, more shrubby in shade |
| | 6 | Cascara | *Rhamnus purshiana* | 2, 11, 22, 23 | 8 - 10m | M | PS | May-Jun | | Grows well on wet, disturbed sites, inconspicuous flowers produce blue-black berries. Bark is powerful laxative |
| | 7 | Black Hawthorn | *Crataegus douglasii* | 13,16, 23, 24 | 6 - 8m | M | S, PS | May | | Copious thorns resist beavers. White flowers, black berries, small tree or broad shrub likes organic soil. scarlet in autumn |
| | 8 | Rocky Mountain Juniper | *Juniperus scopulorum* | 10, 19, 32, 40 | 6 - 15m | D, M | S | n/a | | Great for poor, rocky or sandy soils, tolerate salt spray, replace cedar hedge. Try *J. communis* for groundcover |
| | 9 | Sitka Mountain Ash | *Sorbus sitchensis* | 7, 20, 35, 39 | 1 - 4m | M | S, PS | Jun | | White flower clusters, showy red fruit, red fall leaves, small tree or shrub with leaflets that don't need raking up! |
| | 10 | Saskatoon | *Amelanchier alnifolia* | 12, 14, 16, 29 | 1 - 5m | D, M | S, PS | Apr-May | | Showy white flowers, delicious fruit, spreading rhizomes. Drought, salt and clay tolerant. Deer browse leaves |
| | 11 | Indian Plum | *Oemleria cerasiformis* | 17,15, 20, 24 | 1.5 - 5m | D, M | Sh, PS | Mar | | Hedge or borders, very early flowering, cucumber-tasting plums in May; use male & female plants to ensure fruiting |
| | 12 | Red-flowering Currant | *Ribes sanguineum* | 10, 11, 16, 29 | 1 - 3m | D, M | S, PS | Apr-Jun | | Very showy with early blooms, no thorns, crinkly maple-like leaves on a compact shrub. Dark fruits eaten by birds |
| | 13 | Nootka Rose | *Rosa nutkana* | 7, 19, 20 | 0.5 - 3m | M, WD | S, PS | May-Jul | | Large, fragrant, lilac-pink flowers, large rose hips are reddish-orange, stabilizes stream banks, keeps people at bay |
| | 14 | Oceanspray | *Holodiscus discolor* | 16, 19, 23, 34 | 1 - 4m | D, M | S, PS | Jul-Aug | | Big, showy flower clusters become puffball orange-brown seed heads. Grows taller in shade. Top ten pick! |
| | 15 | Red Elderberry | *Sambucus racemosa* | 17, 18, 20, 24 | 2 - 4m | M | PS | Apr-Jun | | Fast growing shrub, showy white flower clusters attract hummingbirds, shiny red berry clusters and big leaves |
| | 16 | Mock Orange | *Philadelphus lewisii* | 11, 14, 22, 29 | 3m | D, WD | S, PS | May-Jun | | Early fragrant white flowers, fast-growing, adaptable, broad upright shrub. Dense seasonal screening |
| | 17 | Red-osier Dogwood | *Cornus sericea* | 13, 15, 19, 20 | 1 - 5m | D, M | Sh, S, PS | May-Jun | | Hardy, fast-growing, white flowers, showy red twigs, brilliant red fall leaves, fruit is white to bluish |
| | 18 | Thimbleberry | *Rubus parviflorus* | 11, 15, 20, 24 | 1.5 - 3m | M | Sh, S, PS | Jun-Jul | | Large, fragrant pink flower produces sweet berries. Spreading streamside shrub forms thickets with snowberry |
| SHRUBS | 19 | Tall Oregon Grape | *Mahonia aquifolium* | 12, 13 ,23, 24 | 1 - 2m | D, M | S, PS | Apr-May | | Highly recommended! Tough holly-like leaves, yellow flower clusters, edible blue-black berries, dry slope stabilizer |
| | 20 | Pacific Ninebark | *Physocarpus capitatus* | 11, 15, 17, 18 | 3 - 4m | M | Sh, S, PS | Jun | | "Snowball bush" likes wet, open places like streams and lake shores, excellent for securing slopes. Attractive bark |
| | 21 | Evergreen Huckleberry | *Vaccinium ovatum* | 19, 23, 34, 39 | 1 - 2m | D, M | Sh, PS | Apr-May | | Bushy with leathery, shiny, leaves, pink, bell-shaped flowers, sweet, glossy edible purple berries - harvest after frost |
| | 22 | Trumpet Honeysuckle | *Lonicera ciliosa* | 5, 6 , 10, 16 | up to 10m | D, WD | Sh, PS | May-Jul | | A vigorous vine with orange tubular flowers followed by clusters of red berries in the fall. Climbs decks and trees |
| | 23 | Sword Fern | *Polystichum munitum* | 5, 24, 38, 39 | 0.3 - 1.2m | D, M | Sh, S, PS | n/a | | Grows fast, protects shady slopes, adapts to sun, glossy leathery dense fronds provide cover for amphibians |
| | 24 | Salal | *Gaultheria shallon* | 19, 23, 38, 39 | 1 - 1.5m | D, M | Sh, S, PS | Mar-Jul | | Excellent cover for shade and sandy soils, Berries make delicious jelly. Tough, shiny leaves can be pruned back. |
| | 25 | Aster | *Aster conspicuus* | 12, 30, 31, 32 | 35 - 80cm | D, M | S | Jul -Aug | | Bumblebees love the violet blooms with yellow centers, creeping rhizome fills perennial beds |
| | 26 | Nodding Onion | *Allium cernuum* | 27, 28, 29, 30 | 20 - 40cm | D | S | Jun-Aug | | Pollinators' delight! Bulbs multiply quickly in sandy soil & rockeries, showy long season bloomer. Easy transplant |
| | 27 | Great Camas & other lilies | *Camassia leichtlinii* | 1, ,2, 28, 30, 32 | 30 - 70cm | D, M | S, PS | Apr-Jun | | Edible bulbs multiply quickly, attractive seed heads for meadows, mix with Common Camas, Fawn lily, Tiger Lily, etc |
| | 28 | Coastal Strawberry | *Fragaria chiloensis* | 26, 29, 31, 32 | 5 - 15cm | D WD | S, PS | Apr-May | | Tasty groundcover with white flowers and sweet berries. Try *F. virginiana* or *F. vesca* for shade. Transplant runners |
| | 29 | Kinnikinnick | *Arctostaphylos uva-ursi* | 3, 26, 28, 33 | 5 - 15cm | D, WD | S, PS | Apr-Jun | | Salt tolerant groundcover forms large mats, takes trampling & gravelly soils. Covers walls, rockeries. Red berries |
| | 30 | Pearly Everlasting | *Anaphalis margaritacea* | 25, 27, 31 | 30 - 60cm | D | S PS | Jul-Sept | | Crisp papery flowers, long bloomer provides late season interest with yarrow and woolly sunflower |
| | 31 | Yarrow | *Achillea millefolium* | 26, 27, 31, 32 | 30 - 50cm | D | S, PS | Jun-Aug | | Tough perennial, large, white, long lasting flower heads, low, feathery foliage |
| | 32 | Woolly Sunflower | *Eriophyllum lanatum* | 3, 25, 27, 30 | 10 - 60cm | D, WD | S | May-Jul | | Long blooming rockery plant with silver-green leaves. Drought tolerant & self-sowing when established. Excellent choice! |
| | 33 | Broad-leaved Stonecrop | *Sedum spathulifolium* | 26, 28, 29, 30 | 15cm | D, WD | S | Jun-Jul | | Showy bright yellow flowers, succulent edible leaves, place in rock outcrops, on concrete. Salt tolerant |
| | 34 | Low Oregon Grape | *Mahonia nervosa* | 12, 36, 37, 40 | 40 - 80cm | D, M | Sh, PS | Apr | | Perennial creeping and low in full sun, erect and tall in semi-shade with larger leaves. Early flowers, tart berries |
| | 35 | Fringecup | *Tellima grandiflora* | 23, 21, 24, 37 | 40 - 80cm | M | Sh, PS | Apr-Jun | | Fragrant white flower spires rise from fuzzy, heart shaped leaves. spreading habit, resists slugs |
| GROUND COVER | 36 | Red Columbine | *Aquilegia formosa* | 24, 35, 38, 40 | 40 - 80cm | WD | Sh | May-Jun | | Perennial adapts to rocky soils and can be used on steep banks, front of border plantings and streamsides |
| | 37 | False Solomon's Seal | *Smilacina racemosa* | 23, 24, 39, 40 | 30 - 100cm | M | Sh, PS | Apr-Jun | | Showy white flowers and red berries, ornamental foliage, shade-tolerant, easy to transplant |
| | 38 | Pacific Bleeding Heart | *Dicentra formosa* | 21, 24, 27, 39 | 25 - 45cm | M | Sh, PS | Feb-Jul | | Rose pink flowers extend above mounds of grey-green lacy foliage that spreads well in shady moist soils |
| | 39 | Wood Sorrel | *Oxalis oregana* | 23, 35, 38, 40 | 5 - 20cm | M | Sh | May-Jul | | Perennial with spreading rhizomes and dainty white flowers enjoyed by gnomes in drifts of soft clover leaves |
| | 40 | False Lily of the Valley | *Maianthemum dilatatum* | 23, 35, 36, 39 | 15 - 25cm | M | Sh, PS | | | Delicate white flowers followed by berries turning red in winter with glossy foliagepreads well in conifer mulch |

**The N-P-K Ratio Explained**

**N - (Nitrogen)**
Energizes vegetative growth.

**P - (Phosphorus)**
Produces expansive roots, flowers, fruits and viable seeds

**K - (Potassium)**
(or potash) Promotes resistance to disease and temperature stress.

# 'Tis The Season

When your favorite fruits & veggies are ripe for the picking.

## Spring

Fruits & vegetables are at their peak when "in-season." This means better quality, lower prices and less energy to get them from the ground to your table.

# What's Eating My Plant?
## How to Recognize Common Pests by the Leaf Damage They Cause

| Damage | Pest |
| --- | --- |
| Deformed leaves, sucking damage | Aphids |
| Discolored leaves, sucking damage | Thrips and mites |
| Chewed or skeletonized leaves | Beetles, caterpillars, and sawflies |
| Leaf galls (abnormal plant growths) | Cynipid wasps, certain aphids, psyllids, and mites |
| Leaf mines (white patterns on leaves) | Beetle, fly, or moth larvae |
| Folded leaves | Caterpillars, tree crickets, and spiders |
| Rolled leaves | Certain mites or some caterpillars |
| Chewed leaves, slime trails | Slugs and snails |

# Gardener's calendar

✓ = Sow indoors ✓ = Sow outdoors

| Vegetable | | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| BEETROOT - Sow seeds outdoors 30 cms between rows, thinning plants to 10 cms apart. Pick when small before the beetroot turn woody. You can eat the young leaves in salads! | Sow | | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | | |
| CARROTS - Make early spring sowings under a cloche. Leave 30 cms between rows, thinning plants to 2 cms apart. Cover plants with fleece to deter carrot fly pests. | Sow | | | ✓ | ✓ | ✓ | | | ✓ | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | |
| PEPPERS - Sow seeds indoors. Wait until the last frost to plant outside into containers on a sunny patio. To encourage bushy growth, pinch out the growing tips when plants are 20 cms tall. | Sow | | ✓ | ✓ | ✓ | | | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | | ☺ | ☺ | ☺ | ☺ | | |
| COURGETTES - Sow seeds indoors, or in a sunny spot outdoors after the last frost, spacing plants 90 cms apart. Mulch around plants and keep well watered. | Sow | | | ✓ | ✓ | ✓ | ✓ | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | ☺ | ☺ | ☺ | ☺ | | | |
| FRENCH BEANS - Sow indoors, planting out after the last frost. Make later sowings outdoors under a cloche. Space plants 15 cms apart. Water regularly. | Sow | | ✓ | ✓ | ✓ | ✓ | ✓ | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | ☺ | ☺ | ☺ | ☺ | ☺ | | |
| LETTUCE - Sow in moist soil 25 cms between rows, thinning plants to 10 cms - Eat the thinnings! Make sowings once a week for continuous supply. Cover with fleece in cold weather. | Sow | | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ |
| PEAS & MANGETOUT - Sow early indoors then outdoors 90 cms between rows with plants 5 cms apart. Support plants with pea sticks. Cover with fleece to deter mice and pigeons. | Sow | | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | | |
| POTATOES - Choose blight-resistant varieties. Dig plenty of organic matter into the soil. Plant 12 cms deep, 40 cms apart with 60 cms between rows. As plants grow bank up the soil to cover the stems. Water well. | Sow | | | | | | | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | ☺ | ☺ | ☺ | ☺ | ☺ | | |
| RADISHES - Sow every 3 weeks outdoors 15 cms between rows, thinning plants to 3 cms for a continuous supply. Pick young before they turn woody. | Sow | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | ☺ | | | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ |
| ROCKET - Grow as a cut-and-come-again crop. Sow outdoors 45 cms between rows, thinning plants to 23 cms apart. Keep well watered, mulch around plants to seal in moisture. | Sow | | | | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | ☺ | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ |
| RUNNER BEANS - Dig lots of organic matter into the soil before sowing. Sow beans indoors, or in a sunny spot outdoors after the last frost. Grow plants up a wigwam of tall canes. Keep well watered. | Sow | | | | ✓ | ✓ | ✓ | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | | ☺ | ☺ | ☺ | ☺ | | |
| SPINACH - Grow as a cut-and-come-again crop. Sow outdoors after the last frost 30 cms between rows, thinning plants to 15 cms. Sow seeds every 3 weeks for a continuous supply. Cover with a fleece in cold weather. | Sow | | | ✓ | ✓ | ✓ | ✓ | ✓ | | ✓ | ✓ | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ |
| SPRING ONIONS - Make sowings outdoors 15 cms between rows every 3 weeks for a continuous supply. No need to thin. Cover with a cloche when the weather turns cold. | Sow | | | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | ☺ | | |
| SWEETCORN - Sow indoors, planting out after the last frost in a sunny spot. As sweetcorn is wind pollenated, group plants in a block, spaced 45 cms apart Water regularly, especially during dry spells. | Sow | | | | | | | | | | | | |
| | Plant | | | | | | | | | | | | |
| | Harvest | | | | | | | ☺ | ☺ | ☺ | ☺ | | |
| TOMATOES - Sow indoors, then plant out 45 cms apart in a sunny spot. Tie single-stemmed ('cordon') varieties to a cane for support and pinch out the sideshoots (these appear just above the leaf joint). | Sow | | | ✓ | ✓ | | | | | | | | |

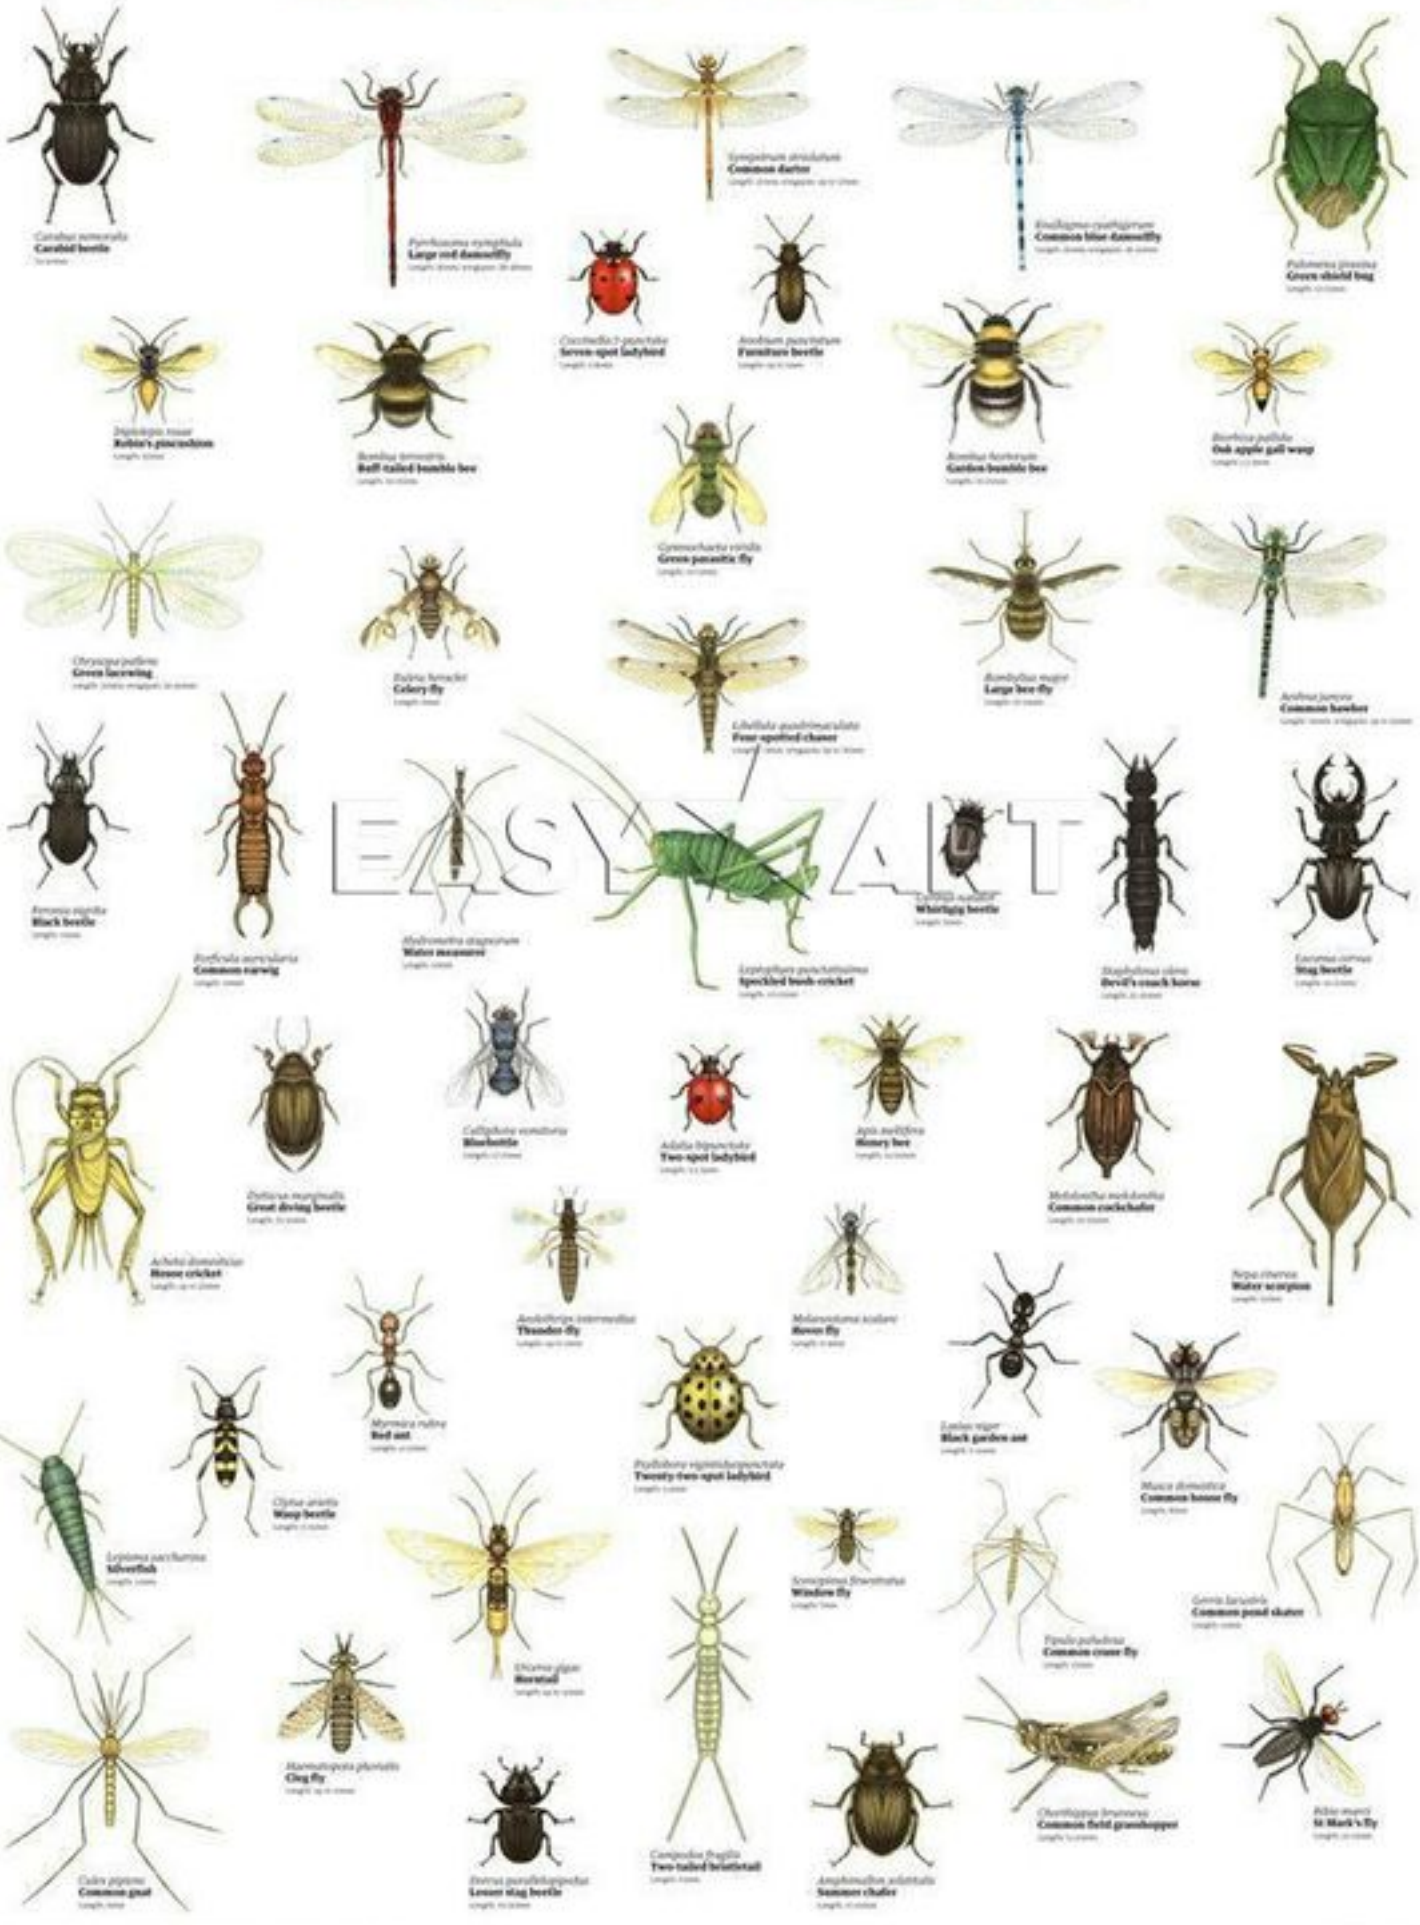
## GARDENING TIPS

- *Successional sowing* avoid gluts of crops - Sow in small quantities every few weeks.
- Do not let your plants go to seed if you wish to continue harvesting them.
- Always read the packets and follow the instructions, if different to above.
- Grow disease and pest free varieties to save time.
- Herbs are easy to grow and look great in pots.
- If you dont have a great deal of space, try sowing lettuces in pots, but remember pots will dry out quicker.
- Take time to water your crops, this is the key to success.
- If you dont have time to sow, buy young plants instead.

# Garden insects



# COMPANION PLANTING

IN NATURAL ECOSYSTEMS, PLANTS PERFORM FUNCTIONS THAT CAN EITHER HELP OR PREVENT OTHER PLANTS TO GROW. THE SAME IS TRUE IN OUR GARDENS. CERTAIN PLANTS GIVE NUTRIENTS BACK TO THE SOIL, WHILE OTHERS NEED TO TAKE UP NUTRIENTS. PLANT AROMAS AND FLOWERS CAN ATTRACT POLLINATORS OR DETER PESTS. BELOW IS A CHART TO HELP YOU UNDERSTAND WHICH PLANTS GROW WELL TOGETHER AND WHICH TO PLANT FAR APART!

| PLANT | GOOD COMPANIONS | BAD COMPANIONS |
|---|---|---|
| BEANS | MAIZE, SUNFLOWERS, LAVENDER, CABBAGE, CUCUMBER, STRAWBERRIES, BRINJAL | ONION, GARLIC, FENNEL |
| BEETROOT | BEANS, ONIONS, GARLIC, LETTUCE, CABBAGE | |
| BRINJAL | CALENDULA, MARIGOLDS, MINT, PEAS | |
| BROCCOLI, CABBAGE, CAULIFLOWER, KALE. | AROMATIC PLANTS, DILL, SAGE, ROSEMARY, POTATOES, BEETROOT, CELERY, GARLIC, ONIONS, GERANIUM | TOMATOES, POLE & RUNNER BEANS, PEPPERS |
| CARROTS | LETTUCE, CHIVES, LEEKS, ROSEMARY, SAGE, PEAS, WOOMWOOD | STRAWBERRIES, FENNEL, CABBAGE |
| LETTUCE | CARROTS, RADISH, STRAWBERRIES, CUCUMBER, BEANS | CELERY, PARSLEY |
| MAIZE | SUNFLOWERS, AMARANTH, BEANS, PEAS, & OTHER LEGUMES, PUMPKIN, SQUASH, CUCUMBER, MELONS, & OTHER CUCURBITS, PARSLEY | CABBAGE, TOMATO, CELERY |
| ONION/ GARLIC | CARROTS, BEETROOT, STRAWBERRIES, TOMATOES, LETTUCE, CABBAGE | PEAS, BEANS, PARSLEY, LEEKS |
| PEAS | LAVENDER, CARROT, TURNIP, RADISH, CUCUMBER, MAIZE, BEANS, GROWS WELL WITH MOST VEGETABLES & HERBS | ONION, GARLIC |
| PEPPERS | TOMATOES, GERANIUM, BASIL, CARROT, ONION | BEANS, KALE, CABBAGE FAMILY |
| POTATOES | CORIANDER, MARIGOLD, BEANS, MAIZE, CABBAGE FAMILY, BRINJAL | PUMPKIN, CUCUMBER, SQUASH, MELONS, SUNFLOWERS, TOMATOES |
| SPINACH | STRAWBERRIES, BROAD BEANS, PEAS | |
| TOMATOES | BASIL, OREGANO/ PARSLEY, CHIVES, NASTURIUM, ONIONS, CARROTS, CELERY, CALENDULA, GERANIUM, BORAGE | POTATOES, FENNEL, CABBAGE FAMILY |
| CALENDULA | TOMATOES- REPELS TOMATO WORM! | GENERAL PEST DETERRANT, PLANT THROUGHOUT GARDEN |
| COMFREY | FAST-GROWING NUTRIENT ACCUMULATOR. PLANT ALONG EDGES & USE LEAVES FOR MULCH | COMPOST ACTIVATOR. USE LEAVES TO MAKE COMFREY TEA FERTILIZER! |
| CHILE PEPPER | CABBAGE, MAIZE | REPELS CABBAGE MOTH. PLANT ON BORDERS TO KEEP FLYING PESTS AWAY! |
| MARIGOLD | PLANT FREELY THROUGHOUT THE GARDEN - REPELS SOIL NEMATODES, APHIDS, BEAN BEETLES & MANY MORE. | USE MARIGOLD LEAVES TO MAKE AN ORGANIC GENERAL INSECTICIDE SPRAY! |
| NASTURTIUM | TOMATOES - IMPROVES FLAVOR! | REPELS WHITE FLIES &" SPIDER MITES |
| THYME | CABBAGE | DETERS CABBAGE WORM |
| ROSEMARY | CARROTS, CABBAGE, SAGE, BEANS | DETERS CABBAGE MOTH, BEAN BEETLES & CARROT FLY! |
| WORMWOOD/ ARTEMESIA | AROUND GARDEN EDGES | KEEPS ANIMALS OUT! ALSO REPELS WHITE FLY |
| YARROW | PLANT FREELY THROUGHOUT THE GARDEN.REPELS SOIL NEMATODES, APHIDS, BEAN BEATLES, AND MANY MORE! | PLANT NEAR AROMATIC HERBS TO ENHANCE ESSENTIAL OIL PRODUCTION |

A DIVERSE GARDEN IS AN ABUNDANT GARDEN. HAPPY PLANTING!

## Annual

A plant that completes its entire life cycle (growth, reproduction, death) in one season.

## Bareroot

These plants have been field-grown and are supplied in a dormant state with the soil removed. E.g **Roses**

## Biennial

A plant that completes its entire life cycle in two years, growing in the ng and dying in the second.

4.4 Google Customer Reviews

## Bolting

To flower and produce seed prematurely.

## Bud union

Refers to the point at which the plant has been grafted on to a rootstock and is usually found at soil level. This is the result of a technique called 'budding' where the bud of one plant is grafted on to another plant.

## Bulb

An underground storage organ with fleshy scale leaves from which the plant flowers and grows before becoming dormant. E.g **Daffodils**.

## Cane

The stems of a raspberry or blackberry plant. Raspberry plants are supplied as dormant canes.

## Chitting

Placing seed potatoes in a tray or egg box in a bright, cool but frost-free place to encourage them to sprout prior to planting.

## Cloche

Structure made of glass, plastic or horticultural fleece placed over a plant for protection or for forcing early crops.

## Cold Frame

Unheated frame for growing on and acclimatising hardy and half-hardy plants outdoors.

## Cordon

A plant carefully trained to grow as one main stem, or occasionally two or three main stems, by removing side-shoots. E.g **tomato plants**.

## Corm

storage organ, consisting of the stem base, outer layer. It is replaced by the plant annually.

4.4 ★★★★½
Google
Customer Reviews

E.g **Begonias**.

## Crown

The growing point of a plant from which new shoots emerge, at or just below the soil surface. E.g **Asparagus**

## Cultivar

A plant that is bred or selected by growers for unique flowers, leaf colour, growing habit etc. It has distinct and uniform characteristics that differ from the original species.

## Dead-head

To remove the spent blooms on a plant to encourage further flowering or to prevent self-seeding.

## Deciduous

A plant that sheds its leaves each year.

## Direct Sow

To sow seeds outdoors in their final positions, where you would like them to flower or crop.

## Earth up

To draw soil up around a plant to exclude light, protect from frost or encourage roots to develop from the stem. This is commonly done with **potato crops**.

## Ericaceous

Used to describe plants that like acid soil and will not tolerate alkaline soils (containing lime or chalk). E.g **Blueberries**.

## Everbearing

Refers to strawberry varieties that yield a small crop in early summer, a few berries throughout the rest of the summer, and another heavier crop during late summer and early autumn.

4.4 ★★★★½
Google
Customer Reviews

First generation offspring derived from breeding two distinct pure-bred lines. They are vigorous and uniform plants. Seeds produced from **F1 Hybrids** will not come true to their parents.

## Feathered Maiden

A one-year old tree with several side branches (feathers).

## First Early Potatoes

These are harvested 10 weeks after planting and will produce new or baby potatoes.

## Floricane

Refers to raspberry and blackberry stems that grow for one year before bearing fruit and flowers e.g. summer-fruiting raspberries and blackberries.

## Germination

Refers to the point at which a seed undergoes physical changes and begins to grow.

## Grafting

Where one plant is artificially joined to the rootstock of another so they eventually function as one plant.

## Half-hardy annual

A plant that completes its entire life cycle (growth, reproduction, death) in one season. Can be grown outdoors but requires winter protection from frosts and temperatures below 0C.

## Half hardy biennial

A plant that completes its entire life cycle in two years, growing in the first year and reproducing and dying in the second. Can be grown outdoors but requires winter protection from frosts and temperatures below 0C.

## Half-hardy bulb/ corm/ rhizome/ tuber

4.4 ★★★★½
Google
Customer Reviews

Plant that grows from an underground storage organ. Generally supplied in a dormant condition with no top growth. Can be grown outdoors but requires winter protection from frosts and temperatures below 0C.

## Half-hardy perennial

A plant that lives for more than two years. Can be grown outdoors but requires winter protection from frosts and temperatures below 0C.

## Half-hardy tree/ shrub

Woody plant, usually having a permanent framework of branches. Can be grown outdoors but requires winter protection from frosts and temperatures below 0C.

## Harden off

To acclimatise young plants that are growing in a protective environment, to cooler conditions outdoors. This is normally achieved by leaving plants outside during the day and bringing them undercover at night.

## Hardy annual

A plant that completes its entire life cycle (growth, reproduction, death) in one season. Capable of withstanding outdoor winter temperatures down to -15C.

## Hardy biennial

A plant that completes its entire life cycle in two years, growing in the first year and reproducing and dying in the second. Capable of withstanding outdoor winter temperatures down to -15C.

## Hardy bulb/ corm/ rhizome/ tuber

Plant that grows from an underground storage organ. Generally supplied in a dormant condition with no top growth. Capable of withstanding outdoor winter temperatures down to -15C.

## Hardy perennial

4.4 ★★★★½
Google
Customer Reviews

re than two years. Capable of withstanding
tures down to -15C.

## Hardy tree/ shrub

Woody plant, usually having a permanent framework of branches. Capable of withstanding outdoor winter temperatures down to -15C.

## Haulm

Another name for the leaves and stems of a potato plant.

## Herbaceous plant

A non-woody perennial plant, often dying back in the winter and becoming dormant by means of underground rootstocks or a woody base. Growth resumes in the spring.

## Lime

Calcium compounds, often applied to lower the pH of the soil (make it more alkaline); particularly useful when growing brassicas (cabbages, broccoli etc) to prevent club root disease.

## Long canes

These are **raspberry canes** which are supplied at a more mature stage of their life and will produce fruit in their first season. The canes supplied are longer than usual (1.25-1.4m).

## Maiden tree

A young tree, generally less than a year old, that can be trained into any form required.

## Maincrop potatoes

These are harvested up to 20 weeks after planting and are good for winter storage. They are good for baking, roasting and mashing.

## Mulch

Layer of material placed on the soil and around plants to retain moisture, suppress weeds and improve soil structure. Materials used for mulching include well-rotted manure, compost, polythene sheets or gravel.

4.4 ★★★★½
Google
Customer Reviews

Substance of animal or plant origin – such as compost, leaf mould or manure. Useful for improving soil structure and supplying nutrients to plants.

## Perennial

A plant that lives for more than two years.

## Pinching out

Removing the growing points of a young plant to encourage side-shoots to form. This encourages a bushy habit and more flowering stems. To find out more about 'pinching out' view our easy to follow video guide by **clicking here**.

## Pollination

The transfer of pollen between flowers, which can be carried out by the wind, insects, animals or by hand.

## Pot on

To remove a plant from its container (normally when it has outgrown the space) and place it into a new container for further growth.

## Pot up

To place seedlings and cuttings into containers to grow on.

## Prick out

To remove and transfer seedlings into pots or module trays to give them more space to grow.

## Primocane variety

Refers to the first-year stems of raspberries and blackberries. **Autumn-fruiting raspberries** will produce flowers and fruit on primocanes (they produce fruit in their first year of growth).

## Propagate

To grow plants from seed or by vegetative means e.g. cuttings or

4.4 ★★★★½
Google
Customer Reviews

## Rhizome

A horizontal fleshy stem which grows at or below ground level. Rhizomes produce roots and shoots.

## Rootstock

The underground part of a plant containing the roots. In grafting, a plant (scion) is joined to a desirable rootstock – often to promote a dwarfing habit.

## Rose End

The end of a seed potato with the most eyes – often the widest end. Potatoes should be chitted with the rose end facing upwards.

## Runner

A trailing stem growing above ground and rooting at the nodes, where plantlets are produced **(e.g. strawberries)**. Some plants produce underground runners.

## Second cropping potatoes

These are planted in late summer/early autumn and harvested about 14 weeks after planting, as for second earlies.

## Second early potatoes

These are harvested about 14 weeks after planting. They make excellent salad potatoes and many varieties are also good for chips, roasting and mashing.

## Seed Potatoes

A potato tuber grown specifically for starting new plants and producing potatoes.

## Self-fertile

A plant that does not need pollen from a second individual in order to fertilise and set fruit.

4.4 ★★★★½
Google
Customer Reviews

A plant that retains most or some of its foliage throughout the year.

## Slips

Cuttings taken from a mature Sweet Potato plant.

## Specimen Plant

Normally a tree or shrub grown in a prominent position where it can be viewed from different angles.

## Standard

A tree or shrub that has been trained to a certain height with a long bare stem and foliage at the top.

## Tender annual

A plant that completes its entire life cycle (growth, reproduction, death) in one season. Susceptible to damage or death at temperatures below 5C.

## Tender biennial

A plant that completes its entire life cycle in two years, growing in the first year and reproducing and dying in the second. Susceptible to damage or death at temperatures below 5C.

## Tender bulb/ corm/ rhizome/ tuber

Plant that grows from an underground storage organ. Generally supplied in a dormant condition with no top growth. Susceptible to damage or death at temperatures below 5C.

## Tender perennial

A plant that lives for more than two years. Susceptible to damage or death at temperatures below 5C.

## Tender tree/ shrub

Woody plant, usually having a permanent framework of branches. Susceptible to damage or death at temperatures below 5C.

4.4 ★★★★½
Google
Customer Reviews

To remove a number of buds, flowers, seedlings or shoots to improve the growth and quality of those remaining.

## Tree/ shrub

Woody plant, usually having a permanent framework of branches.

## Tuber

Swollen root or underground stem with storage tissue **(e.g. a potato)**

# GARDENING TERMS & PHRASES EXPLAINED

Not sure what 'Companion Planting' is? Confused about 'heading back' and 'heeling in'? Here are some common gardening terms explained.

The world of Horticulture can often be a confusing and over technical one, many terms have been used for hundreds of years passed down from generations without their meaning actually being understood. The following is an A-Z listing of some of the most commonly used terms, and a few not so common ones, with a simple explanation of their meaning.

Click a letter to skip to that section - **A**, **B**, **C**, **D**, **E**, **F**, **G**, **H**, **I**, **J**, **K**, **L**, **M**, **N**, **O**, **P**, **Q**, **R**, **S**, **T**, **U**, **V**, **W**, **X**, **Y**, **Z**

## A

**Acaricide** - A **pesticide** used to control mites.

**Acid Soil** - Soil with a pH lower than 7, 7 is neutral and soils over 7 are alkaline. Most plants prefer soils of around 6 - 7. Basic testing kits can be bought at most garden retailers.

**Active Ingredient** - The ingredient in **pesticide** products which is toxic to the target.

**Aerate** - Turning, loosening or driving holes into the ground to aid water and air circulation in the soil. This improves the structure of the soil and makes it easier for roots to grow, breath and get moisture.

**Algicide** - Chemical used to control algae.

**Alkaline Soil**- Soil with a pH greater than 7. 7 is neutral, soils with a pH under 7 are acidic. Most plants prefer soils with a pH of 6-7. Basic testing kits are available at garden retailers.

**Annuals** - A plants whose life cycle takes a year to complete, from seed germination, to flowering, to setting seed and dying.

**Aphids** - Small sap-feeding insects. Maturing into Greenfly and Blackfly.

## B

OK, I agree No, give me more info

**Bacterial Blight** - A bacterial disease causing widespread blackening of leaves and shoots

**Bacterial Canker** - A bacterial disease causing sunken lesions of dead cells in the stem tissue.

**Bareroot** - Plants that are supplied without soil around their roots. Usually they are dug up during their dormant period, rinsed of soil and sold for replanting.

**Bedding Plants** - Usually annual plants, sold for providing a quick, colourful display.

**Biennial** - A Plant whose life cycles takes 2 years to complete, in most cases it will only flower in the second year.

**Black Spot** - One of te most common diseases of Roses, caused by the fungus Diplocarpon rosae.

**Bleeding canker** - A bark disease of deciduous trees usually caused by Phytophthora cactorum. Gunny liquid oozes from lesions in the bark.

**Blossom-end rot** - A non-parasitic disease of tomatoes and peppers. Seen as water-soaked patches on the fruit, caused by calcium deficiency usually linked to irregular watering.

**Bolting** - Usually referring to vegetables, **bolting** is when the plant produces flowers too quickly, rather than producing a food crop. In most cases related to excessive temperatures.

**Bonsai** - A Skillful art of growing miniature plants in small containers.

**Bract** - A group of leaves grown just below a flower or group of flowers. Often mistaken for flowers/petals as with the Poinsettias red bracts.

C

**Catkin** - A slim, drooping group of flowers

**Chlorophyll** - The green pigment in leaves, usually the dominating pigment in a healthy plant.

**Companion Planting** - Growing plants close to each other for beneficial purposes, such as growing flowering plants near your crops to encourage pollinating insects.

**Compost** - A blend of decomposed and decomposing organic materials used for soil improving, mulching, planting and fertilising.

**Corm** - An underground stem which becomes enlarged and produces roots and top growth during the growing season.

**Crown** - The join between the roots and the base of the plant top growth.

**Cultivate** - Turning over and breaking up the surface of the soil, removing large stones, lumps and weeds ready for planting.

**Cuttings** - A propagation method where a new plant is grown from a root, stem or leaf.

OK, I agree No, give me more info

D

**Damping Off** - a fungal disease affecting mainly seedlings and causing the stems to rot at soil level. Usual causes are over-watering, over-crowding and poor air circulation.

**Dead heading** - The act of pinching, pruning or snapping off dead heads of flowers. This will prevent the plant setting to seed and encourage more blooms.

**Dibber** - A tool for making holes in the soil/compost for seeds, seedlings or bulbs.

**Dividing** - Usually done to mature perennials, dividing is the act of splitting the plants roots making multiple plants out of one plant.

**Double digging** - Preparing the soil to the depth of two spade heads, about 10 inches.

**Double flower** - A flower with loads of petals, overlapping and making the flower look big and full.

E

**Evergreen** - A plant which does not lose its leaves all at one time.

F

**Family** - A group used to classify plants. A family will be made up of several similar genera.

**Fertiliser** - Plant foods used to produce more flowers, fruits, root growth and healthier plants. Also used to improve the fertility of soils.

**Forcing** - Speeding up the plants growth to maturity. Usually to see flowers earlier.

**Frond** - Usually referring to 'ferns' or 'palms', the frond is the leaf structure and branches.

**Fungicide** - A **pesticide** used to kill or control fungi.

G

**Genera (Genus)** - A group of closely related plants. In the plant name the genera sits above 'Species' and below 'Family'.

**Germination** - The start of growth in a seed.

**Grafting** - Attaching part of one plant onto another plant, so it grows from the host plants root stock. Usually done to create hardier plants.

H

OK, I agree No, give me more info

**Hardiness** - A means of measuring how tolerant a plant is to cold and frost, without protection.

**Heading back** - Pruning a mature branch back to a stub.

**Heeling in** - Placing the plant in a shallow trench and covering the roots with soil, used as temporary placement until ready to plant up in permanent place.

**Herbaceous** - Used to describe plants which tend to have soft fleshy stems rather than tough woody ones.

**Herbicide** - A type of **pesticide** use to control weeds.

**Horticulture** - The science of cultivating plants.

**Humus** - Dark organic matter in soils, derived from decomposed plant matter.

**Hybrid** - When a new plant is created by cross-pollinating two different species or varieties.

I

**Inflorescence** - The part of the plant that carries the flower.

**Insecticide** - Type of **pesticide** use to control insect pests.

J

**Japonica** - Used in plant names to highlight plants native to Japan (e.g. Fatsia japonica, Skimmia japonica)

K

**K** - The K in N-P-K formula stands for Potassium (from Kalium - plant ashes)

L

**Leaf Mold** - Decomposing leaf matter used to improve soils.

**Leatherjackets** - The larvae of crane flies or daddy long-legs. Adult female lay eggs just below the soil surface usually in grassy areas, the larvae then feed on the roots of the grass causing dead and damaged areas.

**Loam** - A mixture of clay, sand and silt making a rich soil.

M

**Manure** - Organic matter excreted by animals

OK, I agree No, give me more info

**Micro nutrients** - Mineral elements that plants require in very small quantities, micro-nutrients or trace elements can be found in most good garden fertilisers.

**Molluscicide** - A **pesticide** used to control molluscs. (slugs and snails)

**Mulch** - A layer placed over the soil to prevent weeds and lock in soil moisture. Usually organic material, but plastic sheeting is often also used.

N

**Node** - The part of the plant where more leaves, stems or flowers start to grow.

O

**Organic** - Any material which was once a living organism.

p

**Palmate** - Mostly used in horticulture to describe the shape of a leaf, palmate means 'like a hand'. A central point will have segments growing out like fingers. (e.g Acer palmatum)

**Parasitic plant** - A plant that lives on another plant, drawing its nutrients from the host plant. (e.g Mistletoe)

**Perennial** - A plant that lives for multiple growing seasons.

**Pest** - Any living organism causing harm to cultivated plants.

**Pesticide** - Any substance used to kill, control or diminish a pest.

**Pinching out** - Removing fresh growth usually at the top of the plant to promote a fuller, bushier plant.

**Pinnate** - A feather-like leaf structure, with pairs of leaflets either opposite or alternate growing along the main leaf stem. (e.g Robinia)

**Pollination** - The transfer of pollen from the male part of the flower (stamen) to the female part of the flower (pistil) resulting in the formation of a seed.

**Propagation** - The method of starting a new plant. (e.g. seeds and cuttings)

Q

**Quercus** - The latin name for 'Oak'. Latin names often help us understand what a plant looks like. Ilex is the latin name for 'Holly'. So the 'Quercus ilex' is an Oak tree with holly like leaves.

R

OK, I agree No, give me more info

**Raised bed** - A bed raised up higher than ground level, this can provide better drainage, aeration and warmer soils.

**Rhizome** - A plant stem that grows horizontally, usually under the surface of the soil. New plants will grow from various points of the rhizome. (e.g. Iris)

**Root ball** - The mass of roots under the plant with soil attached.

**Runner** - A thin stem growing from the base of a plant, ending with the growing of a new plant. (e.g. Strawberry)

S

**Scarifying** - Raking over the top of a lawn to remove **thatch** and loosen the surface to aid fresh growth.

**Spores** - The reproductive cells of mosses, fungi and ferns. Found in plants that do not produce seeds or flowers.

**Sucker** - New growth coming from the rootstock of a grafted plant. Should be removed as they 'suck' or draw energy from the desired plant.

**Systemic** - The mode of action of a chemical applied to control the pest from within. The chemical is absorbed into the plant and circulated via the sap system, common in **fungicides** (disease control), **insecticides** (bug, insect control) and **herbicides** (weed killers).

T

**Tap root** - The main thick root of a plant, usually growing straight down.

**Tendril** - The thin, twisting and clinging growth of many vines. Used by the plant to attach itself to a surface and climb.

**Thatch** - The layer of dead organic matter on a lawn, this should be removed to aid water, nutrient and light penetration.

**Thinning** - Removing some seedlings to avoid over-crowding and allowing other seedlings to grow with sufficient space. Trees and shrubs can also be thinned by removing older branches.

**Top-Dress** - Spreading soil amendments, fertilisers etc in a thin layer over the soil surface.

**Topsoil** - The top layer of native soil, also referring to soil purchased in bags from garden centres.

**Transplanting** - Taking a plant from its current growing position, and placing it in a new one. Can be in the garden flower beds, or from one pot to another.

**Tuber** - An enlarged underground stem which stores food from which a new plant will grow. ( e.g Dahlia, Begonia)

OK, I agree No, give me more info

U

**Umbel** - A flower cluster that forms a bit like an umbrellas spokes. Flower stems all come from a central point. (e.g. Sambucus - Elderberry)

V

**Variegated** - Leaves which have multiple colours.

**Vermiculite** - When the mineral 'mica' is heated to the point of expansion it creates small spong-like granules. Used to improve aeration and water retention when planting in pots and containers.

W

**Waterlogged** - ground that is saturated and cannot absorb any more water.

**Weeds** - Any plant growing in a place where it is not wanted.

X

**Xanthos** - The Greek for 'Yellow'. Plants with names starting 'Xanth' will have yellow features. (e.g. Xanthorhiza - Xanthos = Yellow, rhiza = root, so this plant has yellow roots.)

Y

**Yarrow** - Achillea millefolium, commonly found growing in lawns and tough to control. Achillea comes from the Greek for Achilles who is said to have discovered its medicinal properties.

**Yield** - The measure of a crop obtained in a harvest.

Z

**Zantedeshia** - Also known as Arum lily and Calla lily. Named after Giovanni Zantedeschi (1773-1846) an Italian botanist and physician.

**Zinc** - A trace element used by plants.

# Gardening Glossary

Learn the language of gardening with this glossary so you'll know what to look for the next time you shop for plants.

## A

**Acid Soil:** Soil with pH less than 7.0. Raise soil pH (lower acidity and raise alkalinity) by adding lime.

**Aerate:** To loosen compacted soil to allow oxygen, water and nutrients to get below the surface. Punch holes into the lawn or remove plugs of soil from the lawn to aerate.

**Amendments:** Organic substances added to the soil to improve moisture retention, oxygen level and nutritive content.

**Alkaline Soil:** Soil that has a pH more than 7.0. Lower soil pH (raise acidity and lower alkalinity) by adding sulfur.

**Annual:** A plant that completes its life cycle in a single year.

**Aphids:** Insects that look like black, yellow, green or white grains of rice. Aphids suck the juices of new growth on plants.

**Apical Bud:** Apical buds, also called terminal buds, are at the tip of a plant stem.

## B

**Balled and Burlapped (B&B):** A method of plant preparation in which the entire root system is contained inside a ball of soil and wrapped in burlap for protection.

**Bareroot:** Dormant plants sold with the roots loose rather than contained in a wrapped soil ball or container.

**Bed:** A specific garden area in which plants are grouped together to create a unified design.

**Biennial:** A plant with a life cycle that spans two years. The plant produces stem and foliage growth during the first year. After a dormant season, they produce flowers and seed the second year.

**Bolt:** When leaf crops (such as spinach and cabbage) stop producing leaves and send up seed stalks due to warming weather.

**Bonsai:** Trained, dwarfed trees and plants in special shallow containers. Bonsai mimics growth in the wild but on a tiny scale.

**Broadcast:** To randomly disperse seeds or other material across a set area.

**Bulb:** An underground-modified stem, usually covered by a papery exterior. Bulbs are the growth and food source for many flowering perennials.

## C

**Cold Frame:** A four-sided structure with a glass or plastic covering used to shelter young plants or transplanted seedlings from cold temperatures.

**Companion Planting:** Adjacent growing of mutually beneficial plants to improve growth and repel pests.

**Compost:** A diverse mixture of completely decayed organic matter used for fertilizing and conditioning soil.

**Conifer:** A woody tree or shrub, primarily evergreen, which produces cones.

**Containerized:** Container-grown trees and shrubs that are ready to transplant along with the soil they've been grown in.

**Corm:** A bulblike structure that serves as a continual underground food source for a flowering plant.

**Crown:** The uppermost part of a tree where new growth takes place or the part of a plant where the roots and stem join.

**Cultivar:** A plant variety resulting from the cross-pollination of two different plants within a species.

**Cultivate:** To assist a plant in the growing process.

**Cuttings:** Portions of root, stem, branch or leaf used to propagate plants.

## D

**Deadhead:** To remove flower heads from plants after they've bloomed to prolong the flowering season.

**Deciduous:** A plant that loses most or all of its leaves in fall or winter.

**Determinate:** A plant that, by artificial or natural means, produces all of its flowers or fruit at the same time.

**Division:** A method of producing new plants from existing stock by digging up the plant, cutting it into two or more pieces and replanting.

**Dormancy:** A period of rest exhibited by no growth or flowering. Dormancy usually takes place during colder periods.

**Double-Digging:** The process of moving the topsoil of one area to another area to reinvigorate the soil.

**Drip Line:** The circumference around a plant formed by water that drips off its outermost leaves or branches.

## E

**Espalier:** A method of training a plant in a formal pattern against a wall or trellis.

**Evergreen:** A plant that retains its green foliage year-round and is functional for more than one growing season. Coniferous evergreens have needlelike leaves and produce seed in their cones. Broadleaf evergreens have regular leaf-shaped foliage but retain their leaves throughout the year.

# F

**Fertilizer:** A supplement to a naturally occurring element necessary for plant growth. Fertilizer can be liquid or granular and organic or inorganic (man-made).

**Foliar:** Pertains to the leaves (foliage) of a plant. Foliar fertilizers and pesticides are applied directly to the leaves.

**Forcing:** To force plants, by artificial means, to mature quickly and produce their flowers earlier than normal.

**Friable:** A characteristic of good soil. Rich in organic matter, friable soil crumbles easily, allows water and oxygen to reach plant roots.

# G

**Germinate:** The process where a seed develops into a sprout. The requirements may be warmth, water or light according to the plant variety.

**Graft:** A propagation method performed by joining two plants by connecting the tissues of each.

**Groundcovers:** Low-growing, spreading plants used for ornamental purposes or as a substitute for grass.

# H

**Half-Hardy:** Refers to plants that can withstand long periods of damp or cold weather but may be damaged by frost.

**Harden Off:** The process of increasing an indoor plant's exposure to light and colder temperatures to acclimate it to outdoor conditions.

**Hardscape:** Constructed elements of a landscape, such as decks, walls fences and driveways.

**Hardy:** Refers to plants that have the ability to survive prolonged exposure to freezing temperatures.

**Heel In:** A method of protecting a plant by placing its stems in a shallow trench over winter.

**Herbaceous:** Refers to nonwoody (soft-stemmed) perennial plants that often die back to the ground every winter and reappear in the spring.

**Herbicide:** A pesticide formulated to kill or control plants.

**Hoop Stake:** A long, thin, metal post with a perpendicular ring of wire at the top, which serves as a support for tall-growing flowers.

**Humus:** Dark, rich, organic soil matter made from decaying plant or animal material.

**Hybrid:** A plant that's the offspring of two parent plants of differing varieties, species or cultivars.

# I

**Indeterminate:** A plant that continues to produce flowers or fruit throughout the duration of the growing season.

**Insecticide:** A pesticide formulated to kill or control insects.

# L

**Lateral Bud:** Buds formed on the sides of a stem.

**Layering:** A method of plant propagation by which a single stem of a plant is notched and buried with its leafy tip exposed, while still attached to the parent plant.

**Leaching:** Occurs when water flushes mineral substances and nutrients out of the soil.

**Leggy:** Refers to plants that have an abnormal amount of stem in relation to their flower and foliage.

**Lime:** Soil amendment used to reduce acidity. Lime (calcium carbonate) is applied in powdered or pelletized form.

**Loam:** Ideal garden soil that has a well-balanced moisture of sand, silt and clay.

## M

**Microclimates:** Small areas in the home landscape that have unique characteristics regarding sun, shade, wind or moisture.

**Mulch:** Any organic material spread on top of soil to reduce water loss or prevent the growth of weeds.

## N

**Naturalize:** A method of random garden plant distribution that simulates the growth of plants in the wild.

## O

**Offshoots:** New plants that branch out from the base of a plant's main stem.

**Organic:** A method of gardening without using synthetic (man-made) products.

**Ornamental:** A plant raised for aesthetic reasons.

## P

**Pavers:** Stone, brick or concrete materials used for patios and walkways.

**Pesticide:** Any substance or mixture of substances intended for preventing, destroying, repelling or mitigating any pest.

**Perennial:** There are two types: herbaceous and woody. Herbaceous, nonwoody (soft and fleshy) plants die back each year and grow, and bloom each successive year. Woody perennials (such as shrubs and trees) have a period of dormancy but maintain their form year-round.

**Perlite:** A mineral used in potting mix to retain moisture and provide aeration.

**pH:** A measurement of acidity and alkalinity. pH represents hydrogen ions in the soil and signifies a plant's ability to draw nutrients from the soil.

**Pinch Back:** A method of encouraging bushy plant growth by removing the growing tip.

**Plugs:** Circular pieces of sod that are planted in a grid formation to start a new lawn.

**Propagate:** To grow new plants from old ones by using one of a variety of methods.

## R

**Retaining Wall:** A barrier created with stones, timbers or boards to prevent the erosion of soil on steep slopes.

**Rhizome:** A horizontal, fleshy underground stem or runner. Creeping grasses spread by rhizomes or stolons.

**Rootbound:** Container-grown plants that lack adequate space for root growth.

**Rootstock:** Refers to the portion on grafted plants that's chosen for the qualities of its root system.

**Row Cover:** Nylon or synthetic netting used to cover young seedlings to protect them from predators.

# S

**Scarify:** To prepare a seed for planting by cutting or nicking the outer layer.

**Scion:** Refers to the portion on grafted plants that's chosen for its superior leaf or fruit production.

**Shrub:** A deciduous or evergreen plant with woody stems that's usually less than 15 feet tall at maturity.

**Side Dress:** To apply fertilizer in a circle or band around plants or rows of plants.

**Soil Test:** A measurement of major nutrient (phosphorous, potassium and nitrogen) and pH levels in the soil.

**Staking:** A method of supporting tall, upright-growing plants by tying their stems to a wood or metal post.

**Standard:** A plant that's trained, through pruning or staking, to the form of a tree.

**Stolon:** A horizontal, fleshy aboveground stem or runner. Creeping grasses spread by rhizomes or stolons.

**Stratify:** To prepare a seed for planting by soaking it in water and then placing it in a warm or cold area.

**Sucker:** A shoot that grows from a plant's roots or from beneath the surface of the ground.

# T

**Taproot:** The first root to grow from a germinating seed. Usually growing straight down, taproots help anchor the plant in the soil.

**Tender:** Refers to plants that are susceptible to frost and may not be able to survive freezing temperatures.

**Terminal Bud:** The uppermost bud on a stem.

**Thinning:** To cut branches or stems back to the main branch to allow sunlight into the plant's center, provide air circulation and encourage remaining stems to grow in their normal direction.

**Thatch:** A layer of plant debris that accumulates between the soil and the grass blades and prevents the flow of moisture, air and nutrients to the grass roots.

**Top Dressing:** To feed plants by sprinkling fertilizer or compost on top of them.

**Topiary:** The art of pruning and shaping trees and shrubs into decorative shapes.

**Topsoil:** The uppermost layer of soil that's the site for a plant's root growth and contains the most organic matter.

**Training:** A method of controlling plant growth, especially on climbing plants, by tying the stems to a support and pruning the plant back regularly.

**Tuberous:** Refers to plants possessing thick and fleshy underground roots that serve as sites for food storage.

**Turfgrass:** Refers to residential lawn grasses as well as varieties used in sports venues.

# V

**Variety:** A naturally grown or cultivated type of plant species.

**Variegation:** A pattern of stripes or patches on otherwise solid-colored leaves.

**Vermiculite:** A mineral used in potting mix to retain moisture and provide aeration.

# W

**Weed and Feed:** Fertilizer that contains weed killer for broadleaf weeds, such as dandelions or grassy weeds such as crabgrass.

**Weeds:** Unwanted plants that grow rampantly through other plantings, competing for food, water and light.

**Woody:** Refers to hard-stemmed perennial plants that are capable of surviving cold weather without dying back.

# X

**Xeriscaping:** To create a lower-maintenance landscape with native plants and reduced areas of turfgrass. A primary goal of xeriscaping is reducing landscape water consumption.

# Plant List

California's native flora is widely celebrated and renowned for its abundance and diversity which is largely due to our climate and varied geology, physiography and soils. This list of plants includes over 100 popular California native species and cultivars that can be grown across the Inland Empire. Many of these plants are organized into garden styles and helpful lists to assist in making good planting choices for beautiful, water conserving gardens.

As you review these plants it is important to remember: (1) The water needs of natives varies; some are adapted to low amounts of water while others do best with moderate moisture. (2) Native plants need care and maintenance. Mulching, weeding, seasonal pruning and replacement are important practices for any garden. (3) Most gardens have a variety of microclimate and moisture conditions as well as many sizes of spaces and activities. Creating a diverse planting palette is encouraged as a means to achieve both beauty and to find plants that fit soil, moisture and microclimate conditions.

# Plant List

## *Acacia farnesiana*

Common Name: **Sweet acacia**
Plant Type: **Tree, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **20 ft. - 25 ft.** Width: **20 ft. - 25 ft.**

## *Calocedrus decurrens*

Common Name: **Incense cedar**
Plant Type: **Tree, Native**
Water Needs: **Moderate 3**
Exposure: **All day sun**
Height: **40 ft. - 80 ft.** Width: **10 ft. - 20 ft.**

## *Chilopsis linearis + cvs*

Common Name: **Desert willow**
Plant Type: **Tree, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **15 ft. - 40 ft.** Width: **15 ft. - 40 ft.**

## *Cupressus arizonica + cvs*

Common Name: **Arizona cypress**
Plant Type: **Tree, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **35 ft. - 50 ft.** Width: **5 ft. - 15 ft.**

Exposure: **All day sun**
Height: **20 ft. - 30 ft.** Width: **12 ft. - 15 ft.**

## Plant List

### *Lyonothamnus floribundus ssp. asplenifolius*

Common Name: **Fern-leaf Catalina ironwood**
Plant Type: **Tree, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun**
Height: **25 ft. - 50 ft.** Width: **25 ft. - 35 ft.**

### *Lysiloma watsonii*

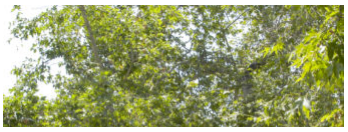
Common Name: **Feather bush**
Plant Type: **Tree**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **12 ft. - 15 ft.** Width: **12 ft. - 15 ft.**

### *Parkinsonia x* 'Desert Museum'

Common Name: **Desert Museum palo verde**
Plant Type: **Tree, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **20 ft. - 30 ft.** Width: **20 ft. - 25 ft.**

### *Pinus torreyana*

Common Name: **Torrey pine**
Plant Type: **Tree, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **60 ft. - 80 ft.** Width: **30 ft. - 45 ft.**



Common Name: **Western sycamore**
Plant Type: **Tree, Native**
Water Needs: **Moderate 3**

## Plant List

### *Quercus agrifolia*

Common Name: **Coast live oak**
Plant Type: **Tree, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **30 ft. - 60 ft.** Width: **40 ft. - 70 ft.**

### *Quercus engelmannii*

Common Name: **Engelmann oak**
Plant Type: **Tree, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **25 ft. - 60 ft.** Width: **25 ft. - 60 ft.**

### *Quercus tomentella*

Common Name: **Island oak**
Plant Type: **Tree, Native**
Water Needs: **Low 2**
Exposure: **All day sun, Partial sun**
Height: **35 ft. - 50 ft.** Width: **20 ft. - 30 ft.**

### *Umbellularia californica*

Common Name: **California bay**
Plant Type: **Tree, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Partial sun**
Height: **30 ft. - 50 ft.** Width: **30 ft. - 50 ft.**

Common Name: **California fan palm**
Plant Type: **Palm, Native**
Water Needs: **Low 2**

## Plant List

### Shrubs

### *Abutilon palmeri*

Common Name: **Indian mallow**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **6 ft. - 8 ft.** Width: **6 ft. - 8 ft.**

### *Arctostaphylos* 'Howard McMinn'

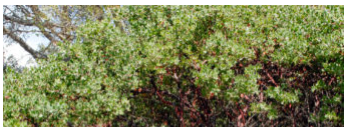
Common Name: **McMinn manzanita**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun**
Height: **6 ft. - 8 ft.** Width: **6 ft. - 8 ft.**

### *Arctostaphylos* 'John Dourley'

Common Name: **Dourley manzanita**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun**
Height: **3 ft. - 4 ft.** Width: **5 ft. - 6 ft.**

### *Arctostaphylos* 'Lester Rowntree'

Common Name: **Lester Rowntree manzanita**
Plant Type: **Shrub, Native**



## *Arctostaphylos* 'Sunset'

Common Name: **Sunset manzanita**

Plant Type: **Shrub, Native**

# Plant List

Height: **5 ft. - 7 ft.** Width: **5 ft. - 7 ft.**

## *Arctostaphylos bakeri* 'Louis Edmunds'

Common Name: **Louis Edmunds manzanita**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, Partial sun**
Height: **8 ft. - 10 ft.** Width: **6 ft. - 8 ft.**

## *Arctostaphylos glauca*

Common Name: **Bigberry manzanita**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **12 ft. - 15 ft.** Width: **15 ft. - 20 ft.**

## *Artemisia californica*

Common Name: **California sagebrush**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 5 ft.** Width: **5 ft. - 7 ft.**

## *Artemisia californica* 'Montara'

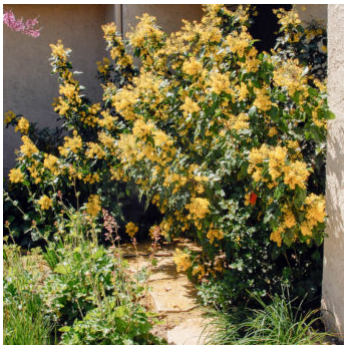
Common Name: **Montara sagebrush**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **All day sun**

Common Name: **Coyote brush**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**

## Plant List

### *Baccharis sarothroides*

Common Name: **Broom baccharis**
Plant Type: **Shrub**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **10 ft. - 12 ft.** Width: **10 ft. - 12 ft.**



### *Berberis* 'Golden Abundance'

Common Name: **Golden Abundance barberry**
Plant Type: **Shrub**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Partial sun**
Height: **6 ft. - 8 ft.** Width: **6 ft. - 10 ft.**

### *Berberis nevinii*

Common Name: **Nevin's barberry**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**
Exposure: **All day sun, Partial sun**
Height: **8 ft. - 12 ft.** Width: **8 ft. - 12 ft.**

### *Calycanthus occidentalis*

Common Name: **Spice bush**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade**
Height: **8 ft. - 10 ft.** Width: **8 ft. - 10 ft.**

Common Name: **Bush anemone**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**

## Plant List

### *Ceanothus* 'Concha'

Common Name: **Concha wild lilac**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun**
Height: **6 ft. - 9 ft.** Width: **6 ft. - 10 ft.**

### *Ceanothus* 'Dark Star'

Common Name: **Dark Star wild lilac**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 6 ft.** Width: **6 ft. - 10 ft.**

### *Ceanothus* 'Joyce Coulter'

Common Name: **Creeping mountain lilac**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 2**
Exposure: **All day sun, Partial sun**
Height: **3 ft. - 5 ft.** Width: **10 ft. - 12 ft.**

### *Ceanothus* 'Julia Phelps'

Common Name: **Small leaf mountain lilac**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **5 ft. - 8 ft.** Width: **6 ft. - 9 ft.**

Common Name: **Ray Hartman wild lilac**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Cercis occidentalis*

Common Name: **Western redbud**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade, All day sun, Partial sun**
Height: **15 ft. - 20 ft.** Width: **15 ft. - 20 ft.**

### *Cercocarpus betuloides*

Common Name: **Western mountain mahogany**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **10 ft. - 15 ft.** Width: **10 ft. - 15 ft.**

### *Dendromecon harfordii*

Common Name: **Island bush poppy**
Plant Type: **Shrub**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **6 ft. - 10 ft.** Width: **6 ft. - 10 ft.**

### *Encelia californica + cvs*

Common Name: **California bush sunflower**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **3 ft. - 5 ft.** Width: **3 ft. - 5 ft.**

Common Name: **Incienso, Brittlebush**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Eriogonum arborescens*

Common Name: **Santa Cruz Island buckwheat**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 5 ft.** Width: **5 ft. - 6 ft.**

### *Eriogonum cinereum*

Common Name: **Ashyleaf buckwheat**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 5 ft.** Width: **4 ft. - 6 ft.**

### *Eriogonum fasciculatum*

Common Name: **Common buckwheat**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **2 ft. - 3 ft.**

### *Eriogonum giganteum*

Common Name: **St. Catherine's lace**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **8 ft. - 10 ft.** Width: **8 ft. - 10 ft.**

Common Name: **Cliff buckwheat**
Plant Type: **Shrub**
Water Needs: **Low 2**

## Plant List

### *Fallugia paradoxa*

Common Name: **Apache plume**
Plant Type: **Shrub**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **4 ft. - 5 ft.** Width: **4 ft. - 5 ft.**

### *Fremontodendron* 'California Glory'

Common Name: **Flannel bush**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **15 ft. - 20 ft.** Width: **15 ft. - 20 ft.**

### *Galvezia juncea*

Common Name: **Baja bush-snapdragon**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **3 ft. - 6 ft.** Width: **3 ft. - 6 ft.**

### *Galvezia speciosa + cv*

Common Name: **Island snapdragon**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **3 ft. - 4 ft.** Width: **8 ft. - 10 ft.**

Common Name: **Toyon**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Hyptis emoryi*

Common Name: **Desert lavender**
Plant Type: **Shrub**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: Width:

### *Isomeris arborea*

Common Name: **Bladderpod**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 6 ft.** Width: **4 ft. - 6 ft.**

### *Justicia californica*

Common Name: **Chuparosa**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **4 ft. - 6 ft.** Width: **6 ft. - 8 ft.**

### *Lupinus albifrons*

Common Name: **Silver bush lupine**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 5 ft.** Width: **4 ft. - 6 ft.**

Common Name: **Sticky monkey flower**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**

## Plant List

### *Prunus ilicifolia ssp. ilicifolia*

Common Name: **Hollyleaf cherry**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Moderate shade, All day sun, Partial sun**
Height: **15 ft. - 30 ft.** Width: **15 ft. - 30 ft.**

### *Prunus ilicifolia ssp. lyonii*

Common Name: **Catalina Cherry**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **30 ft. - 45 ft.** Width: **20 ft. - 30 ft.**

### *Rhamnus californica + cvs*

Common Name: **Coffeeberry**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **8 ft. - 10 ft.** Width: **8 ft. - 10 ft.**

### *Rhamnus crocea*

Common Name: **Redberry**
Plant Type: **Shrub**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **6 ft. - 8 ft.** Width: **6 ft. - 8 ft.**

Common Name: **Lemonade berry**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Rhus lentii*

Common Name: **Pink-flowering sumac**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 8 ft.** Width: **5 ft. - 6 ft.**

### *Rhus ovata*

Common Name: **Sugar bush**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **8 ft. - 35 ft.** Width: **20 ft. - 25 ft.**

### *Ribes aureum*

Common Name: **Golden currant**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **Morning sun, All day sun**
Height: **6 ft. - 10 ft.** Width: **5 ft. - 7 ft.**

### *Ribes malvaceum*

Common Name: **Chaparral currant**
Plant Type: **Shrub**
Water Needs: **Low 1**
Exposure: **Moderate shade, Partial sun**
Height: **4 ft. - 6 ft.** Width: **4 ft. - 6 ft.**

Common Name: **Red flowering currant**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**

## Plant List

### *Ribes speciosum*

Common Name: **Fuchsia-flowered gooseberry**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, All day sun**
Height: **4 ft. - 6 ft.** Width: **4 ft. - 6 ft.**

### *Rosa californica*

Common Name: **California wild rose**
Plant Type: **Shrub, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade**
Height: **3 ft. - 6 ft.** Width: **8 ft. - 10 ft.**

### *Salvia* 'Allen Chickering'

Common Name: **Allen Chickering sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 4 ft.** Width: **3 ft. - 4 ft.**

### *Salvia* 'Pozo Blue'

Common Name: **Pozo Blue sage**
Plant Type: **Shrub**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **3 ft. - 4 ft.** Width: **3 ft. - 4 ft.**

Common Name: **White sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Salvia brandegeei*

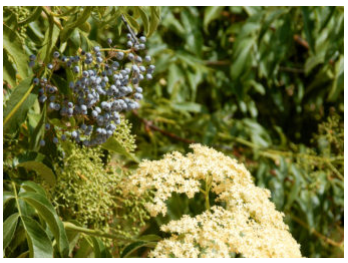
Common Name: **Santa Rosa Island sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **4 ft. - 5 ft.** Width: **5 ft. - 7 ft.**

### *Salvia clevelandii* 'Winifred Gilman'

Common Name: **Winifred Gilman sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 5 ft.** Width: **3 ft. - 5 ft.**

### *Salvia mellifera*

Common Name: **Black sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 6 ft.** Width: **3 ft. - 6 ft.**



### *Sambucus nigra ssp. mexicana*

Common Name: **Blue elderberry**
Plant Type: **Shrub, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **10 ft. - 25 ft.** Width: **10 ft. - 25 ft.**

Common Name: **Jojoba, Goatnut**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**

## Plant List

### *Trichostema lanatum*

Common Name: **Woolly blue curls**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **3 ft. - 4 ft.**

## Vines

### *Clematis lasiantha*

Common Name: **Chaparral clematis**
Plant Type: **Vine**
Water Needs: **Low 1**
Exposure: **Morning sun, Partial sun**
Height: **12 ft. - 18 ft.** Width: **12 ft. - 18 ft.**

### *Vitis californica + cv*

Common Name: **California grape**
Plant Type: **Vine, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade, All day sun**
Height: **30 ft. - 40 ft.** Width: **30 ft. - 40 ft.**

## Perennials

### *Achillea millefolium + cvs*

Exposure: **Moderate shade, All day sun**
Height: **18 in. - 30 in.** Width: **18 in. - 30 in.**

## Plant List

### *Armeria maritima*

Common Name: **Common thrift**
Plant Type: **Ground cover, Perennial, Native**
Water Needs: **Moderate 4**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **6 in. - 8 in.** Width: **10 in. - 12 in.**

### *Artemisia pycnocephala*

Common Name: **Sandhill sage**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **8 in. - 12 in.** Width: **18 in. - 24 in.**

### *Asclepias fascicularis*

Common Name: **Narrow leaf milkweed**
Plant Type: **Perennial**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 4 ft.** Width: **2 ft. - 3 ft.**

### *Asclepias subulata*

Common Name: **Desert Milkweed**
Plant Type: **Perennial, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **3 ft. - 4 ft.** Width: **3 ft. - 4 ft.**

Common Name: **Desert Marigold**
Plant Type: **Perennial**
Water Needs: **Low 2**

## Plant List

### *Epilobium canum*

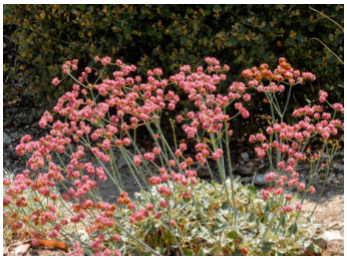
Common Name: **California fuchsia**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 4 ft.** Width: **3 ft. - 4 ft.**

### *Erigeron glaucus + cvs*

Common Name: **Beach aster, Seaside daisy**
Plant Type: **Perennial, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, All day sun**
Height: **10 in. - 12 in.** Width: **24 in.**

### *Eriogonum crocatum*

Common Name: **Saffron buckwheat**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **12 in. - 18 in.** Width: **18 in. - 24 in.**



### *Eriogonum grande var. rubescens*

Common Name: **Red buckwheat**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **2 ft. - 3 ft.**

Common Name: **Sulphur buckwheat**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**

## Plant List

### *Fragaria vesca*

Common Name: **California strawberry**
Plant Type: **Ground cover, Perennial**
Water Needs: **Moderate 3**
Exposure: **Moderate shade, Partial sun**
Height: **2 in. - 8 in.** Width: **2 ft. - 6 ft.**

### *Heuchera cultivars*

Common Name: **Coral bells**
Plant Type: **Perennial, Native**
Water Needs: **Moderate 3**
Exposure: **Moderate shade, Partial sun**
Height: **12 in. - 15 in.** Width: **12 in. - 15 in.**

### *Heuchera maxima*

Common Name: **Island alum root**
Plant Type: **Perennial, Native**
Water Needs: **Moderate 3**
Exposure: **Moderate shade**
Height: **12 in. - 18 in.** Width: **12 in. - 18 in.**

### *Iris douglasiana + cvs*

Common Name: **Douglas iris**
Plant Type: **Perennial, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade**
Height: **12 in. - 18 in.** Width: **12 in. - 24 in.**

Common Name: **Fragrant pitcher sage**
Plant Type: **Perennial**
Water Needs: **Moderate 3**

## Plant List

### *Lessingia filaginifolia* 'Silver Carpet'

Common Name: **Silver carpet aster**
Plant Type: **Ground cover, Perennial**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **4 in.** Width: **2 ft. - 3 ft.**

### *Lupinus excubitus*

Common Name: **Grape soda lupine**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **3 ft. - 4 ft.**

### *Monardella odoratissima*

Common Name: **Desert mint**
Plant Type: **Perennial**
Water Needs: **Low 1**
Exposure: **All day sun, Partial sun**
Height: **1 ft.** Width: **3 ft.**

### *Penstemon centranthifolius*

Common Name: **Scarlet bugler**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **12 in. - 18 in.**

Common Name: **Firecracker penstemon**
Plant Type: **Perennial**
Water Needs: **Low 2**

## Plant List

### *Penstemon heterophyllus* 'Margarita BOP'

Common Name: **Margarita foothill penstemon**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **1 ft. - 2 ft.** Width: **1 ft. - 2 ft.**

### *Penstemon spectabilis*

Common Name: **Showy penstemon**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft. - 5 ft.** Width: **2 ft. - 3 ft.**

### *Romneya coulteri + cv*

Common Name: **Matilija poppy**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **6 ft. - 10 ft.** Width: **6 ft. - 10 ft.**

### *Salvia spathacea*

Common Name: **Hummingbird sage**
Plant Type: **Perennial, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, Moderate shade, Partial sun**
Height: **12 in. - 18 in.** Width: **12 in. - 18 in.**

Common Name: **Desert mallow**
Plant Type: **Perennial, Native**
Water Needs: **Low 2**

## Plant List

### *Verbena lilacina* 'De La Mina'

Common Name: **Lilac verbena**
Plant Type: **Perennial, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **2 ft. - 3 ft.**

## Grasses, Rushes and Sedges

### *Aristida purpurea*

Common Name: **Purple three-awn**
Plant Type: **Grass, Native**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **18 in. - 24 in.** Width: **24 in. - 30 in.**

### *Bouteloua gracilis*

Common Name: **Blue grama**
Plant Type: **Grass**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **18 in. - 24 in.** Width: **12 in.**

### *Carex divulsa*

Common Name: **Berkeley sedge**
Plant Type: **Grass, Sedge**

## *Carex pansa*

Common Name: **California meadow sedge**
Plant Type: **Ground cover, Grass, Sedge, Native**

# Plant List

Height: **8 in. - 10 in.** Width: **12 in. - 24 in.**

## *Carex praegracilis*

Common Name: **Western meadow sedge**
Plant Type: **Ground cover, Grass, Sedge, Native**
Water Needs: **Moderate 4**
Exposure: **Morning sun, Moderate shade, All day sun**
Height: **12 in. - 15 in.** Width: **12 in. - 15 in.**

## *Festuca californica*

Common Name: **California fescue**
Plant Type: **Grass, Native**
Water Needs: **Low 1**
Exposure: **Partial sun**
Height: **1 ft. - 2 ft.** Width: **1 ft. - 2 ft.**

## *Juncus patens*

Common Name: **California gray rush**
Plant Type: **Grass, Rush, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade, All day sun**
Height: **18 in. - 24 in.** Width: **18 in. - 24 in.**

## *Juncus textilis*

Common Name: **Basket rush**
Plant Type: **Grass, Rush, Native**
Water Needs: **Moderate 4**
Exposure: **Morning sun, Moderate shade, All day sun**

Common Name: **Wild rye**
Plant Type: **Grass, Native**
Water Needs: **Low 1**

## Plant List

### *Muhlenbergia rigens*

Common Name: **Deer grass**
Plant Type: **Grass, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **2 ft. - 5 ft.** Width: **3 ft. - 6 ft.**

### *Nassella pulchra*

Common Name: **Purple needle grass**
Plant Type: **Grass, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **18 in. - 24 in.** Width: **18 in. - 30 in.**

### *Sporobolus airoides*

Common Name: **Alkalai sacaton**
Plant Type: **Grass, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **1 ft. - 4 ft.** Width: **1 ft. - 4 ft.**

## Agaves, Cacti, Dudleyas and Yuccas

### *Dudleya species*

Common Name: **Dudleya**
Plant Type: **Succulent, Native**

## *Hesperoyucca whipplei*

Common Name: **Our Lord's candle**

Plant Type: **Yucca, Native**

# Plant List

Height: **3 ft. - 4 ft.** Width: **6 ft.**

## Ground Covers

## *Arctostaphylos* 'Pacific Mist'

Common Name: **Pacific Mist manzanita**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **2 ft. - 3 ft.** Width: **6 ft. - 10 ft.**

## *Arctostaphylos edmundsii* 'Carmel Sur'

Common Name: **Carmel Sur manzanita**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 2**
Exposure: **Morning sun, Moderate shade, All day sun**
Height: **18 in.** Width: **7 ft. - 10 ft.**

## *Arctostaphylos hookeri* 'Monterey Carpet'

Common Name: **Monterey Carpet manzanita**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, Moderate shade, All day sun**
Height: **1 ft. - 2 ft.** Width: **8 ft. - 12 ft.**

## *Artemisia californica* 'Canyon Gray'

Common Name: **Canyon Gray sagebrush**

Plant Type: **Shrub, Ground cover, Native**

## Plant List

### *Baccharis pilularis* 'Pigeon Point'

Common Name: **Pigeon Point Coyote brush**
Plant Type: **Shrub, Ground cover**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **18 in. - 24 in.** Width: **6 ft. - 9 ft.**

### *Berberis aquifolium* 'Compacta'

Common Name: **Oregon grape**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade**
Height: **18 in. - 24 in.** Width: **3 ft. - 5 ft.**

### *Berberis repens*

Common Name: **Creeping barberry**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Moderate 3**
Exposure: **Morning sun, Moderate shade**
Height: **18 in. - 30 in.** Width: **2 ft. - 3 ft.**

### *Ceanothus thyrsiflorus var. griseus* 'Yankee Point'

Common Name: **Yankee Point wild lilac**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 2**
Exposure: **Morning sun, All day sun, Partial sun**
Height: **2 ft. - 3 ft.** Width: **10 ft. - 12 ft.**

Common Name: **Theodore Payne buckwheat**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**

## Plant List

### *Iva hayesiana*

Common Name: **Hayes iva, Poverty weed**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Moderate 3**
Exposure: **All day sun**
Height: **2 ft. - 3 ft.** Width: **4 ft. - 5 ft.**

### *Lessingia filaginifolia* 'Silver Carpet'

Common Name: **Silver carpet aster**
Plant Type: **Ground cover, Perennial**
Water Needs: **Low 2**
Exposure: **All day sun**
Height: **4 in.** Width: **2 ft. - 3 ft.**

### *Ribes viburnifolium*

Common Name: **Evergreen currant**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **Morning sun, Moderate shade**
Height: **5 ft. - 7 ft.** Width: **5 ft. - 7 ft.**

### *Salvia* 'Bee's Bliss'

Common Name: **Bee's Bliss sage**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **1 ft. - 3 ft.** Width: **5 ft.**

Common Name: **Mrs. Beard sage**
Plant Type: **Shrub, Ground cover, Native**
Water Needs: **Low 1**

## Plant List

### *Salvia leucophylla* 'Point Sal Spreader'

Common Name: **Point Sal purple sage**
Plant Type: **Shrub, Native**
Water Needs: **Low 1**
Exposure: **All day sun**
Height: **3 ft.** Width: **6 ft.**

# A California-Friendly Guide to Native and Drought Tolerant Gardens

LAS VIRGENES MUNICIPAL WATER DISTRICT
EST. 1958

Scale: 1/4” = 1’

**WELCOME** to our newest edition of ***"A California-Friendly Guide to Native and Drought Tolerant Gardens",*** a collection of plants featured in our customer newsletter, ***The Current Flow***, plus useful information. This publication is intended to help beginning and experienced gardeners become familiar with the different varieties of plants that can help reduce water usage while providing a pleasing and attractive landscape.

Native and drought tolerant plants are important for this region, not just because they are water efficient, but because they are the cornerstone of biological diversity and the foundations of the native ecosystems in our local Santa Monica Mountains environment. Using "California-friendly" plants for everything from backyard gardens to wide scale re-vegetation is a positive practice that will benefit the local habitat and all residents who live here.

With our current climate conditions of increasing warmth and less moisture, more and more Californians are becoming interested in replacing high-maintenance, lawns that require a lot of water and fertilizers, with water-conserving plants. These can be anything from ground covers to a field of meadow flowers to stately oak trees – they all provide the benefits of lower water needs, reduced maintenance requirements, restored soil health, increased diversity that attracts birds and butterflies, as well as the aesthetic beauty of blending in with the natural landscapes.

Visit www.LVMWD.com for conservation information including irrigation tips, how to obtain and use Community Compost, rebate programs, how to register for landscape and garden classes, controlling urban runoff, and more.

LVMWD hopes this publication will help you get started on your journey to a waterwise garden and landscape.

Happy Gardening!

# Community Compost

## What is Community Compost?

Community Compost is a natural product with a high humus content similar to peat. It is the end product of the environmentally sensitive solids handling process at Rancho Las Virgenes Composting Facility. Biosolids from Tapia Water Reclamation Facility are transformed through a composting process into an excellent soil amendment that can be used to enhance landscapes, ornamental areas, lawns, and vegetable gardens. This compost has been used at the Getty Museum, Palm Springs golf courses, and other locations throughout California.

## How Can I Get My Free Supply?

How: Bring a container(s) with a cover, or strong plastic bags with ties, or a tarp to cover the bed of your pick-up truck. Shovels are provided, but you will be responsible for filling your own container(s).

When: Every Saturday, 8 am to 1 pm

Where: Rancho Las Virgenes Composting Facility, 3700 Las Virgenes Road, Calabasas

For bulk supplies,
call 818.251.2200
for more information.

## What Are the Benefits of Community Compost?

As a soil amendment, Community Compost increases water-holding capacity of light soils, enhances aeration in heavy soils, and provides slow-release nutrients for plant growth. As an alternative for biosolids disposal, it transforms waste into a beneficial product, offers a long-term disposal method and diverts material from landfills.

## How Should Community Compost Be Used?

Community Compost is an effective soil conditioner when applied as a topdressing to established lawns, flower beds and gardens, and as an amendment to all soils for new seed lawns or landscape. The organic, slow release of nutrients is less susceptible to loss through leaching than conventional fertilizers. Soils which are low in organic matter, highly compacted, with a low water infiltration rate, and suffering from poor nutrient content or lacking water-holding capacity can benefit from the addition of Community Compost.

Vegetable Gardens...EPA regulations allow the use of Community Compost on vegetable gardens, not to exceed one cubic yard per 1,000 square feet per year.

Flower Beds...For new flower gardens, use 3 cubic yards of Community Compost per 1,000 square feet (about 1-2 inches and incorporate to at least a 5-6 inch depth). Amend established gardens every other year with about 1/2 cubic yard of compost.

Also note, using more than recommended levels will stimulate vegetative growth and fewer flowers. Do not use on acid-loving flowers without adjusting the pH.

Planters...To make potting soil for outdoor or indoor planters, mix 1 part Community Compost to 2 parts soil mix. Mix the media components until uniform, plant your seeds/bulbs and water thoroughly.

Trees & Shrubs...Dig a planting hole 4 times the width of the tree or shrub, and save the soil to mix 2 parts to 1 part of Community Compost. Place a portion of the mixture in the hole and then the tree or shrub. Add the remainder of the mixture around the plant, occasionally firming it, to secure the root ball, then water thoroughly.

Community Compost may be used as a substitute for peat moss or milled pine bark and fertilizer.

Lawns...Top dress established lawns by uniformly applying 1-1/2 cubic yards of Community Compost per 1,000 square feet (1/2 inch) once a year.

Rancho Las Virgenes Composting Facility
3700 Las Virgenes Road, Calabasas, CA 91302
www.LVMWD.com

### Product Boundaries

Compost will improve soil properties, such as lower bulk density and increase water infiltration and retention. However, compost will not fulfill all plant nutrient requirements and should be used in combination with fertilizers for optimum results.

Compost is not to be used to grow mushrooms as a food crop. Compost is hygienically and environmentally safe if it is used properly but it can become a hazardous nuisance if mismanaged.

As with all gardening products, wash your hands after using Community Compost. Use common sense and good hygiene when handling compost. Also, as with any product containing nitrogen, do not introduce Community Compost into any body of water. Avoid run-off when watering lawns and flower beds after its application.

# Slope Stabilization

To help avoid erosion and runoff on your property, put in some native plants to stabilize the soils, control erosion and reduce your future irrigation costs. Moist and cool months are ideal to start these "soil keepers". Once established they will require little irrigation. A mixture of plants is best, with various root depths to hold up a slope. In addition, a sprinkling of native seeds will add to the immediate coverage of your slope.

## Blue-eyed Grass[4]

*Sisyrinchium bellum*

Delicate flowers, abundant from February to May, with grass-like leaves. A perennial, found naturally in grass meadows and other open places, re-seeds easily. A lovely addition to a dry border and does well in containers with well-draining soil. Likes sun to partial sun exposure. Foliage will die back in summer heat. 1'h x 1'w

## California Fuschia[27]

*Zauschneria californica*

Reference books may list this as *Epilobium canum*. A very hardy native that can take a lot of abuse, this is commonly found in dry areas, rocky slopes and cliffs. Abundant, scarlet tubular flowers from July to November, popular with hummingbirds. Likes sun to partial sun exposure, may be used as a ground cover. 2'h x 4'w

## California Redbud[8]

*Cercis occidentalis*

An interesting plant year round, with beautiful pea-shaped magenta flowers on leafless stems in the spring, followed by interesting seedpods and heart-shaped blue-green leaves. Deciduous, with yellow or red fall foliage on multi-branching stems. Prefers sun exposure. Excellent for dry, seldom watered banks. 20'h x 15'w

## Twinberry Honeysuckle[5]

*Lonicera involucrata*

Prefers moist areas and pruning will keep size under control. Dense foliage with unique orange-red flowers that produce berries, attractive to birds. Blooms in the spring, drops leaves in winter. Sun to partial shade exposure. 6'h x 6'w

# Arid Plants

Many areas in our region are hot and dry for many months. Consider these water-efficient, drought tolerant selections for added variety in your landscaping and savings on your water bills. Each plant can be an attractive feature, massed with others, or on its own.

## Santa Barbara Ceanothus[2]

*Ceanothus impressus*

A large shrub with a dense mass of dark wrinkled green leaves, covered with deep blue flower clusters in early spring, mostly March to April. Requires good drainage and infrequent to no summer watering, can be temperamental, preferring sun to partial sun exposure. 6-10'h x 6-10'w

## Tree Poppy[1]

*Dendromecon rigida*

Large shrub with linear gray foliage and showy bright yellow, poppy-like flowers that bloom from February to June. Thrives in dry, well-drained soil, can adapt to various soil conditions. Good for banks, roadsides, preferring sun to partial sun exposure. Prune back after flowering to control untidy wild growth pattern. 3-10'h x 4-8'w

## Golden Yarrow[2]

*Eriophyllum confertiflorum*

An abundant perennial small shrub found naturally at the base of cliffs in rock crevasses, preferring sun exposure. Finely leafed foliage, green above and woolly below. Blossoms are clusters of yellow flowers, displayed from March to August, attractive to butterflies. 2-4'h x 1-4'w

## Showy Penstemon[1]

*Penstemon spectabilis*

Found naturally in chaparral and coastal sage scrub zones, this perennial is a perfect choice for drought tolerant gardens. Truly spectacular lavender-pink-purple flowers, April to June, are found on two-foot spikes above coarse textured leaves. May naturalize and prefers sun to partial sun exposure. Attractive to hummingbirds. 2-3'h x 3'w

# Drought Tolerant "Extremists"

To reduce the amount of water used outdoors, consider a "California-friendly" landscape with drought tolerant plants. This is especially important in times of little rain – you can create an attractive waterwise garden, save money, and help prevent urban runoff. The following are very drought tolerant once established.

## Mesa Bushmallow[32]

*Malacothamnus fasciculatus*

This medium shrub bears many small pink flowers on foot long stems covering the gray-green foliage in the spring and summer. This is a good slope stabilizer or hedge plant. 3-12'h x 6'w

## Canyon Live-Forever[1]

*Dudleya cymosa*

This evergreen succulent has rosette leaves with red-orange flowers in spring and early summer. Prefers full sun, good drainage and does well in containers or rock gardens. 1'h x 1'w

## Matilija Poppy[1]

*Romneya coulteri*

This perennial shrub may be a bit tricky to get established, but is worth the effort. It requires excellent drainage and lots of sun. Large 4-6" crinkled flowers appear from spring to summer. Spreads by underground rhizomes. 3-5'h x 8'+w

## Desert or Apricot Mallow[1]

*Sphaeralcea ambigua*

A very hardy evergreen perennial, this plant has coral flowers clustered on stems spring to fall. Prefers dry winters and benefits from pruning after it blooms. 3'h x 3'w

# Native Trees

The cooler moist time of year provides an ideal climate for young natives, especially young trees, to get established. Soils are still warm from summer and the roots can spread and grow. Trees are an investment in your future – aesthetically and as cooling sunshades for your home and yard.

## California Sycamore[2]

*Platanus racemosa*

A fast grower, with multi-branches that can be trained into attractive shapes. It likes sun, moderate water and can take wind and heat, but is drought tolerant once established. Large palm-shaped leaves are woolly on both sides in spring and change to a soft brownish yellow in the fall. The mottled bark results from thin layers that drop off, exposing greenish to whitish areas beneath. An important wildlife species, used extensively by hummingbirds and butterflies. 40'h x 30'w

## Fremont's Cottonwood[2]

*Populus fremontii*

Extremely fast growing, this tree likes moist conditions, but can tolerate drought. Bright shiny green triangular leaves flutter in the wind and turn a lemon-yellow in the fall. An excellent shade tree, the males do not produce cotton. Cottonwoods are important bird and butterfly plants. Do not plant near septic systems or under power lines, as their root growth pattern and height can be problematic. 40-60'h x 35-40'w

## Pacific Wax Myrtle[2]

*Myrica californica*

With its dense fragrant foliage, this makes an excellent screen or hedge plant that will tolerate wind. The spring flowers are inconspicuous, but the fall purplish wax-covered fruits are attractive to birds. Requires good drainage. Tolerates drought and prefers sun to partial shade. 10-25'h x 10'+w

## California Bay Laurel[3]

*Umbellularia californica*

A fine shade tree often with multi-trunks, with evergreen, aromatic leaves and yellow flowers from December to May. The small fruits are inedible. Grows best in deep soil with ample water, but tolerates drought. With dense foliage, this tree makes a good screen or can be trimmed into a formal hedge. 80'h x 25'w

# Oaks Native to Southern California

Oaks provide shade, fall color, and sustenance for a complex network of insects, birds, and other wildlife. Oak trees can thrive with a minimum of maintenance and irrigation, once established.

Much of California's landscape features oak-dotted hillsides. To grow and care for an oak is to invest in the future as lifespans of hundreds of years are not uncommon for these trees.

Several species of native oaks are found in this area. The southern range for Valley Oaks runs through our area. Interior Live Oaks, Coast Live Oaks and Scrub Oaks are common sights on the rolling hillsides and open spaces that surround our communities.

## Coast Live Oak[23]

*Quercus agrifolia*

This evergreen tree provides deep, wide shade with holly-like leathery dark green leaves, tooth edged, 1-3" long. Thick moist bark helps protect tree against fires. 20-70'h x 35'+w

## Scrub Oak[12]

*Quercus beberidifolia*

A large shrub with dense growth, variable leaves, usually ¾ - 1½" long, medium green on top, grayish on bottom, and wavy edges. Good as clipped hedge or background. 6-15'h x 6-15'w

## Valley Oak[1]

*Quercus lobata*

This deciduous tree with crooked branches and checked gray bark is a trademark of valley grasslands. Leaves are deeply cut, round-lobed 3-4" long, 2-3"wide, dark green on top, paler on bottom. Tolerant of heat. 15-70'h x 35-70'w

## Interior Live Oak[22]

*Quercus wislizenii*

A tree with a dense, rounded crown, is often wider than high. Glossy, elliptical, green leaves are 1-4" long with smooth or spiny edges and abruptly pointed tip. Tolerant of shade. 30-75'h x 30-40'w

# Perennial Penstemons

Easier to grow locally than anywhere else in the world, most penstemons are drought tolerant and most are native to the western states, found in the desert heat, on mountainsides, and in mild coastal zones. All require at least six hours of sun daily and well-drained soil that is loose and gravelly. Too much water and too rich a soil will accelerate their decline. Tubular flowers come in a variety of colors ranging from indigo blue to red/orange and pink. Any selection will be a welcome addition to the landscape and will attract hummingbirds as well.

## Scarlet Bugler[3]

*Penstemon centranthifolius*

This penstemon has scarlet red blossoms with blue-gray foliage, a long bloom season, and is very drought tolerant. This plant prefers hot, dry summers and mild winters to perform well. 1-3'h x 3'w

## Panamint Beard Penstemon[1]

*Penstemon floridus*

A large showy perennial, this plant combines coarsely serrated to smooth leaves with hot pink flowers atop tall spikes. Prefers hot, dry summers and cold winters. 3-4'h x 3'w

## Cleveland's Beardtongue[2]

*Penstemon clevelandii*

Rose pink flowers with gray foliage make this an attractive garden plant. Prefers hot summers and mild winters. 2-3'h x 2'w

## Palmer's Penstemon[11]

*Penstemon palmeri*

Very large and fragrant pale pink blossoms with gray foliage make this a beautiful plant. Grows with a very erect form, is attractive to hummingbirds, and is appropriate for areas with cold winters. 3'h x 3'w

# Barren Spaces

Turn highly visible garden spots (along a fence, a driveway, or a sidewalk) that are parched into an oasis with plants that need little care or water. Planting a variety of bulbs, evergreen perennials and shrubs, or ornamental grasses will create an eye-pleasing bright spot. These waterwise species fill in quickly and, once established, remain low enough to not block traffic views.

## Firecracker Penstemon[11]

*Penstemon eatonii*

This is a desert species with bright red flowers that bloom from spring to summer, on long evergreen stalks. Prefers full sun, good drainage, and will attract hummingbirds. Does better with some water in the summer. 3-4'h x 3-4'w

## Western Blue Flax[1]

*Linum lewisii*

This is a splendid small perennial with an interesting texture. Many 1" blue to white flowers cover the plant in early spring. Keeps its shape better if trimmed back after blooming. Prefers full sun. 1-2'h x 1-2'w

## Douglas Iris[1]

*Iris douglasiana*

Planted as a rhizome, this species grows linear, vase-shaped evergreen foliage and produces many beautiful light-purple, blue, white, or cream flowers in the spring. Tolerant of heavy soils and garden conditions, prefers sun to partial sun. 1'h x 2'w

## Sulphur Buckwheat[1]

*Eriogonum umbellatum*

Brilliant yellow flowers bloom in the spring on stems above mounds of pretty oval foliage. Very drought tolerant, it prefers full sun and will attract hummingbirds. 1'h x 3'w

# Grasses

Often overlooked when selecting plants for the garden, grasses add so much – dramatic backgrounds, soft edges, interesting foliage colors and textures ranging from spiky to soft and silky. These varieties are very drought tolerant.

## Sheep Fescue[10]

*Festuca ovina "Glauca"*

This is a clumping grass with soft, tough leaves that form blue-gray tufts. Useful as a ground cover in sunny to partially shaded areas and on slopes. Needs little water. Clip to enhance appearance; replant as small divisions. 4-10"h x 1'w

## Deergrass[12]

*Muhlenbergia rigens*

Provides interesting texture contrast, with many erect narrow blades that fan out in vase-shaped foliage, in dense clumps. Stays evergreen without summer water. 1-3'h x 2-3'w

## Purple Needle Grass[13]

*Nassella pulchra*

This native bunch grass is a good addition to wild garden settings. Purplish flowers bloom before it matures in summer to golden yellow. Remains dormant until winter rains. 2'h x 2'w

## Giant Wild Rye[16]

*Elymus condensatus*

A tall, erect clumping perennial useful in the back of a border garden. Distinct silver blue-gray foliage complements bluish flower plumes in summer. Native to San Miguel Island (Channel Islands), found locally in the zone between plant communities. 4-8'h x 3-6'w

# Under Oak Trees

It takes a special plant to successfully grow beneath one of our local oak trees. It has to tolerate shade from the broad tree canopy, and thrive in the dry conditions that are essential for the oak's survival in the dry periods of the year. When planting under an oak, remember to not plant, irrigate, or disturb the soil within 10 feet of the trunk, and avoid injuring the roots. Also, plant sparingly; use drip irrigation or soaker hoses, not sprinklers. And finally, it is best to not plant under declining older oaks.

## Alum Root Hybrids[4]

*Heuchera maxima hybrids*

This evergreen perennial plant displays foliage clumps 1–2' across, with shiny dark-green, round, heart–shaped leaves. Flowers range from whitish to pinkish. Hundreds of blossoms form in each narrow 2–3' long cluster that attracts hummingbirds. Blooms February to April, and makes a good ground cover or border. Looks very delicate but is quite drought tolerant and cold resistant. Plant about 2' apart with bark or chip covering as a 2–4" mulch. 1'h x 2'w

## Hollyleaf Cherry[1]

*Prunus ilicifolia*

The mature leaves of this plant are a deep, rich green, resembling holly leaves. New leaves are a lighter green, creating a pleasant contrast with the older foliage. Creamy white flower spikes appear with the new leaves in March. Birds are attracted to the fruit, which turns from green to red, then reddish purple. Does best in coarse, well-drained soils. Has an unusually high resistance to oak root fungus. 3-20'h x 10'w

## Hummingbird Sage[3]

*Salvia spathacea*

This evergreen perennial has 2-3'whorls of red-magenta flowers on upright stems attractive to hummingbirds. Blooms appear spring to summer. It has large arrow-shaped fragrant leaves and will spread to form a nice mat via rhizomes. Likes at least 15" of rainfall per year, and will grow in a variety of soil types. 3½'h x 3'w

## Pink-flowering Currant[3]

*Ribes sanguineum var. glutinosum*

A deciduous shrub, this plant has long, graceful pink flowers, 15–40 in a cluster. Blooms from January to March and produces blue black berries. This is one of the most attractive native species in our area. Will tolerate a range of soil conditions, and is moderately drought tolerant. 3-8'h x 5'w

# Spring Flowers and Butterflies

Below are just a sampling of native plants that offer springtime blooms and are attractive to various stages of the butterfly lifecycle. They will add a variety of textures, colors, and shapes to the landscape and are efficient users of water. Butterfly larvae (caterpillars) need food plants and adults need nectar varieties. Sunny areas that are protected from the wind will be the most appealing to the local and migrating "flutter-bys". Avoid pesticides unless you can target the garden pest without harming these interesting visitors.

## Common Yarrow[2]

*Achillea millefolium*

A perennial/groundcover that spreads by its roots, this specimen presents 3-4" clusters of small white flowers above evergreen foliage that is delicate and finely textured. Adult butterflies enjoy this plant. Medium drought tolerant, it likes sun to partial sun. Excellent when used in a garden border or as a lawn substitute as it can be mowed. Widely adapted to variety of soil conditions. 4-6"h x 3'w

## Scarlet / Western Columbine[2]

*Aquilegia formosa*

Delicate orange-red blossoms nod above gray-green lacy foliage from spring to summer. Attracts adult butterflies. Medium to low drought tolerant, this plant prefers a shady location. A favorite garden perennial, cutting first blooms will encourage a second crop (but leave some to reseed). 2½'h x 2'w

## Bigleaf Lupine[7]

*Lupinus latifolius*

A beautiful lupine with long, fragrant rose-purple flowering spikes. Foliage, arranged like spread fingers on a hand, is an attractive gray-green. It is an important food plant for butterfly larvae. It is tolerant of garden conditions, and prefers sun to partial sun. 4'h x 4'w

## Bush Sunflower[1]

*Encelia californica*

A small shrub that looks best in the garden setting if cut back every two years and irrigated in the summer; however, this is useful for out-of-the way places beyond irrigation. Bright yellow daisy-like flowers bloom from February to June. Prefers sun to partial sun location. 3'h x 5'w

# Perennials with Spring Blooms

The following plants have it all: they are water efficient, have attractive flowers in the spring, and remain or return each year. Adding any one to your garden will bring bright color and save on irrigation costs.

## Red Buckwheat[28]

*Eriogonum grande rubescens*

Native to the Channel Islands, this plant is compact and low growing, with gray-green leaves and dark pink blossoms that attract butterflies. 2'h x 2'w

## Scarlet Larkspur[3]

*Delphinium cardinale*

Native to coastal mountains, this perennial rootstock has wide lobed leaves, erect stems and large deep red blossoms that attract butterflies. 3-5'h x 1-2'w

## Beach Suncups[32]

*Camissonia cheiranthefolia*

Naturally found growing in sand dunes, this is a good choice for areas with good drainage. Low growing silver foliage with lemon yellow flowers. 1'h x 3'w

## Coyote Mint[27]

*Monardella villosa*

A California native, this bushy grower has gray-green leaves, purplish flowers, and mint fragrance. Requires good drainage and regular trimming back to maintain shape. 1-2'h x 2'w

# Ground Covers

With a focus on water conservation, consider these drought-tolerant ground cover species as companions or extensions of traditional turf zones in your landscape. Some landscapes require a neat and unobtrusive appearance; in other situations, erosion control is the main function. Ground covers can satisfy many landscape needs. Some can hug the soil or grow into mounds up to 3 feet high and many require minimal maintenance so you save time as well as water. Decide on your specific needs and then enjoy!

## Bearberry or Kinnikinnick[2]

*Arctostaphylos uva-ursi*

A slow growing evergreen ground cover that creates a mat, spreading and rooting as it creeps out. Delicate light pink flowers appear in winter through spring atop dense leathery green leaves. Leaves turn a reddish tint in winter. It is useful on slopes or along retaining walls. Prefers sunny to partially sunny locations. Requires regular water after planting. Once established, depending on soil conditions, will thrive with infrequent summer water. 1'h x 2-3'w

## Wild Strawberry[1]

*Fragaria chiloensis*

Native to Pacific beaches and bluffs, this plant forms lush, compact mats of dark green, glossy leaves that turn reddish in winter. Tolerates sun along the coast to partial shade inland. Large 1"wide white flowers appear in spring. Fruit will seldom set in gardens but in natural setting will produce a seedy fruit in the fall that attracts birds. Annual mowing or cutting back in the early spring will stimulate new growth. Requires some water once established. 6-12"h x 1-2'w

## Rockrose[6]

*Cistus sp.*

A very hardy plant, with showy spring flowers. Accepts poor, dry soil and will tolerate cold ocean winds, salt spray or desert heat. Needs well-drained soil if irrigated. Little to no water is required once established. An occasional trimming of old stems will induce new growth. Height will vary depending on kind. Shorter varieties are useful as ground cover, in rock gardens, and in rough areas along roads or driveways. 1'h x 2-3'w

## Spring Cinquefoil[2]

*Potentilla tabernaemontanii*

This tough and persistent plant has a dainty appearance. A tufted creeper, this plant bears clusters of butter-yellow flowers in spring and summer. Does well in most gardens and will smother out weeds effectively once established. Makes a good lawn substitute in areas of no-traffic. A fast grower, it is well used as a cover for bulbs. Little to moderate water is required. 2-6"h x 1-2'w

# Sages in the Garden

Stars of the western garden, sage varieties grow as annual bedding plants, perennials in the border, shrubs and ground covers, with a variety of foliage and blossom colors. All have a common floral arrangement with whorls of two-lipped flowers either distinctly spaced along the stalk or tightly crowded to appear as one dense spike. The foliage scent ranges from sweet or flavorful to strong. Routine trimming will keep them attractive year-round in the cultured garden. Most are highly drought tolerant and will do well with little to no summer irrigation once established. They are excellent for erosion control on slopes, or for hot, dry locations on the edges of more routinely irrigated areas. Many are favorites of hummingbirds and butterflies.

## Cleveland Sage[9]

*Salvia clevelandii*

One of the best-scented sages, this selection is evergreen with grey-green leaves and stunning lavender blooms. It likes sun and perfect drainage. The intense fragrance will carry 20-50 feet on a warm night. 3'h x 4'w

## Mexican Bush Sage[8]

*Salvia leucantha*

This plant displays long purple spikes in summer and fall that gracefully arch above grayish green foliage. Will take some light shade. Keep tidy and attractive by cutting old stems off at the ground. 3'h x 4'w

## Black Sage[1]

*Salvia mellifera*

An excellent choice for erosion control, this shrub displays light green foliage, and delicate sky blue blooms. Likes sun to partial sun and is also available as a ground cover called 'Tera Seca'. 3-5'h x 6'w

## Purple Sage[1]

*Salvia leucophylla*

Foliage looks silver, with white woolly leaves. A very erect or spreading shrub, its summer blossoms are pinkish to purple. Very drought tolerant, annual trimming of branches will control its spreading pattern. 2-6'h x 3-4'w

# Bulbs

Many types of flower bulbs and corms do well in Southern California. They are worth the effort to locate as they do not require coaxing to bloom and many naturalize easily. Truly gems for the garden, they add variety and require little water or maintenance.

## White Mariposa Lily[11]

*Calochortus venustus*

Native to Southern California Coast Ranges, this bulb blooms from May to July. Flower colors range from white, yellow and purple to dark red, all with the "peacock eye" at the base of the petals. 1'h x 2'w

## Leopard Lily[14]

*Lilium pardalimum*

This perennial California native bulb likes moist shaded areas. In the spring and summer, clusters of large orange or red flowers with brown to maroon spots appear on tall flowering spikes. Leaves and flower stalk die back after blooming. 6'h x 2'w

## Oneleaf Onion[1]

*Allium unifolium*

A California native with lavender to pink flowers that appear in June on tall stems. A good cut flower either fresh or dried. Likes deep, rich, sandy loam soil. 2'h x 2'w

## Harvest Brodiaea[1]

*Brodiaea elegans*

Very common in California, this plant loves sun and heat and requires no summer water. Dark violet to blue flowers appear in late spring to mid summer. Mulch to protect corms from freezing. 2'h x 1'w

# Deer Resistant

Living next to wildlife can be exciting – and frustrating, especially if they are eating your landscape. Deer are well adapted to browse flowers, shrubs and trees. With some planning, you can avoid providing a "deer buffet" and still enjoy the beauty of waterwise plants. In general, deer do not like plants that are prickly, spicy, bitter, tough, hairy, highly aromatic, or furry (see Suitability Lists). However, when natural food for deer is scarce, nothing is safe!

## Western Spice Bush[1]

*Calycanthus occidentalis*

A deciduous shrub that produces red/brown blossoms in the spring. Prefers sun to partial shade and moderate water. Can be trained into a multi-stemmed tree but best used as a background shrub or screen. Blossoms and bruised leaves have an "old wine barrel" fragrance. 6-12'h x 8-12'w

## Sticky Monkeyflower[11]

*Mimulus aurantiacus*

This showy perennial has abundant apricot colored blossoms that will attract hummingbirds. Occasional summer watering will extend the blooming season. Drought tolerant. 1-4'h x 3'w

## Oregon Grape[11]

*Berberis aquilifolium*

An evergreen shrub that does best with regular watering but can tolerate less. Grows in either sun or shade with creeping rhizomes. Buttercup-yellow spring blossoms develop into blue berries that attract birds. A popular landscaping species due to easy maintenance. 6'h x 4'w

## California Redbud[28]

*Cercis occidentalis*

This native shrub presents pea-shaped magenta flowers before the bright green heart-shaped leaves. In the fall, seed pods are produced with yellow foliage. 6-16'h x 20'w

# Container Planting

Ideal for small balconies, patios, or as accent plants, plants in containers can be appreciated year round. They require more care (soil, water, and fertilizers) than plants in the ground, but are worth the effort. Container gardening also provides a way to grow species not suited for local garden conditions. Waterwise plants, including shrubs and small trees, adapt well to container-life; clip back leggy growth for best results.

## Cleveland Sage[9]

*Salvia clevelandii*

One of the best-scented sages, this small evergreen shrub has stunning lavender blooms and gray-green leaves. Likes sun and perfect drainage. Intense fragrance will carry 20-50 feet on a warm night. 3'h x 4'w

## Desert Beauty/Indigo Bush[15]

*Dalea species*

A perennial with springtime purple pea flowers clustered at the ends of silvery green leaf branches. Trim to promote fullness. Infrequent summer watering will prevent partial deciduous leaf drop. 3-5'h x 3-5'w

## Pacific Sedum Stonecrop[1]

*Sedum spathulefolium*

This is a succulent with bright yellow flowers in the spring that are carried above attractive rosette evergreen leaves. An attractive small plant, it prefers sun to partial shade and is highly drought tolerant. 4"h x 1'w

## Alum Roots - Coral Bells[4]

*Heuchera (hybrids)*

This evergreen perennial plant displays foliage clumps with shiny dark-green, round, heart-shaped leaves. Hundreds of whitish to pinkish blossoms form in narrow 2-3 foot long clusters from February to April. Quite drought tolerant, cold resistant and attracts hummingbirds. 10"h x 1-2'w

# Patio or Container Plants

Container gardening provides increased mobility, seasonal variety, and creative opportunities in the landscape. While container plants may require more frequent watering, these California natives are a few of the more efficient water users.

## California Fuschia[27]

*Epilobium canum*

Also referred to as *Zauschneria californica* , the abundant scarlet tubular flowers appear in the fall, looks best when trimmed after flowering or before new growth begins. Attractive to hummingbirds. 1-4'h x 4'+w

## Douglas Iris[1]

*Iris douglasiana*

Evergreen leaves up to 2' long show off flowers on 1-2' stems, ranging in color from purple to blue, and white to cream. Tolerates less than ideal garden conditions. 1'h x 2'w

## Canyon Live-Forever[1]

*Dudleya cymosa*

This is an evergreen succulent with basal rosettes that bloom from spring through summer with red-orange flowers. 1'h x 1'w

## Island Bush Snapdragon[24]

*Galvezia speciosa*

Bright red tubular flowers bloom from spring to summer on this plant that tolerates more shade. Attractive to hummingbirds. 3'h x 6'w

# Landscape for Fire Safety

Fire is a part of the natural cycle in Southern California's Mediterranean climate. The keys to successful "Firewise Landscaping" are plant selection, plant placement, and maintenance. Use plants high in water content and low in available fuel. Reduce mass plantings by spacing trees and large shrubs apart to prevent "fuel ladders". Maintain the landscape with proper trimming, removal of dead wood, and provide appropriate irrigation. The following are examples of what can be used to be fire safe and provide an attractive landscape (see section on Firewise Landscape and Fuel Modification Zones.)

## California Fuchsia[2]

*Zauschneria californica*

Sometimes referred to as *Epilobium canum*, this small shrub can take lots of abuse and still bloom in the fall with brilliant red trumpet flowers that attract hummingbirds. Provides excellent erosion control for steep slopes. 1'h x 4'w

## Coyote Brush[1]

*Baccharis pilularis*

This evergreen "mounding" groundcover can tolerate difficult situations. It is useful for slope stabilization and is extremely drought tolerant. 12-30"h x 4-10'w

## Fairy Duster[12]

*Calliandra eriophylla*

This deciduous shrub is native to Baja California. Once established, it does not require water and produces beautiful clusters of pinkish fluffy flowers in the spring. 3'h x 4-5'w

## Matilija Poppy[1]

*Romneya coulteri*

This spectacular and extremely hardy perennial is native to Southern California. Large fragrant blossoms, up to 6" wide, resemble fried eggs. Root structure helps reduce erosion. Spreads by underground runners and prefers loose, gravelly soil. 5-8'h x 8'w

# Wildfire Area Garden Plants

Every few years we are reminded of how Southern California neighborhoods and open spaces can burn during a wildfire. The following plants are included on the County of Los Angeles Fire Department's list for fuel modification guidelines (see section on Firewise Landscape and Fuel Modification Zones) and are approved for the area 20 feet beyond structures. They require little to moderate irrigation. From a fire defense angle, it is best if most plants in this area are low ground covers and shrubs.

## Woolly Yarrow[29]

*Achillea tomentosa*

This is a groundcover with flat golden flowerheads atop a spreading flat mat of fernlike gray-green, hairy leaves. 6-10"h x 1'w

## Red-Hot Poker[30]

*Kniphofia uvaria*

A plant with a shrub-size clump of grass-like foliage that requires moderate water to bloom and good drainage in winter. Leaves 2' long with dramatic red-orange to yellow blossoms. 3'h x 3-4'w

## Seaside Daisy[1]

*Erigeron glaucus*

Native to California, this groundcover forms clumps of stout stems topped by lavender flowers. Some summer irrigation is best. Tolerant of hot inland conditions. 1'h x 3'w

## Society Garlic[31]

*Tulbaghia violacea*

A popular perennial with bluish-green 1-2' long leaves, this plant produces clusters of many lavender flowers mostly in spring and summer. Prefers well drained soils. Divide clumps to increase plantings. 1-2'h x 2'w

# Native Wildflowers from Seed

Commercial wildflower seed mixtures, available in various sizes of packets, provide wonderful surprises of color and a wild feel to areas of your landscape. Many reseed and die back after blooming. These are a few that are often included.

## California Poppy[1]

*Eschscholzia californica*

A true perennial, this wildflower is often grown as an annual. Color varies from pale yellow to deep orange. Flowers spring to summer and reseeds easily. Blossoms close at night. Plant seeds in fall, broadcasting on well-drained soil. Little irrigation required. 8-24"h x 12"w

## Sky Lupine[1]

*Lupinus nanus*

An annual that covers many local hillsides and fields, likes full sun and loam to clay soil. Pea-shaped spring-time flowers are a rich blue, tipped with white in dense spikes at the end of stems. Plant seeds in fall or winter. Self-seeds readily if there is little competition. Good for barren banks. Little irrigation required. 8-24"h x 9-12"w

## Tidy Tips[1]

*Layia platyglossa*

A showy yellow-white annual, this wildflower prefers clay to loam soil. Plant seeds in fall or early spring in areas of full sun. A rapid grower, blooms appear spring through early summer. Self-seeds and will naturalize on banks if grass is minimal. Very drought tolerant. 6"h x 12"w

## Globe Gilia[12]

*Gilia capitata*

Related to phlox, this annual has 1-2" clusters of spring blue flowers that look like pincushions. Used by many butterflies. Plant seed in fall or early spring in well-drained soil. Likes rocky areas with lots of sun. Little to moderate irrigation required. 8-30"h x 8"w

# Lavenders

Planting a variety of lavender provides blooms almost year round. The different foliage colors, growing habits, and fragrances make this group an outstanding waterwise addition to any local garden. Good drainage is important for success. They also like full sun and air space for circulation. In areas without summer rain, lavenders require some irrigation, more if grown in containers. Slow growing, lavenders reach full size in three years and benefit from annual pruning after the blooming season. For the best color and fragrance, wait until the flower buds have opened, and cut during the cool morning once any dew has dried.

## Spanish Lavender[17]

*Lavandula stoechas*

This is a stocky plant with dark grey-green, narrow leaved foliage. Ranging from purple to pink, the early spring blossoms are small with the top bracts resembling rabbit ears. 1½-2'h x 3-4'w

## Sweet Lavender[10]

*Lavandula heterophylla*

This plant has green foliage with smooth upper leaves and toothed lower leaves that remain evergreen. Bright purple flower spikes add height to overall shape and appear from spring to mid-summer. 2'h x 2-3'w

## French Lavender[10]

*Lavandula dentate*

Narrow grey foliage with serrated edges give this variety its other name of "Toothed Lavender". Purple flowers on short spikes are topped with bracts like rabbit ears and appear from late spring into summer and almost year-round in mild winter areas. 3-4'h x 4-5'w

## English Lavender[17]

*Lavandula angustifolia*

Sweetly fragrant, this is the variety used for perfume and sachets, and it's also the hardiest. The silvery-grey-green foliage is semi-evergreen and most varieties form low growing mounds. Blooms range from white, pink, lavender blue to shades of purple and appear in late summer or fall. 2-4'h x 4'w

# Succulents

Succulents store water in their leaves, stems or roots that help them survive periodic drought. While most are native to warmer parts of the world, not all tolerate summer heat. Succulents are useful as ground covers, erosion controllers, and as decorative additions to local landscapes. Those with sharp tipped leaves need to be carefully situated to avoid foot traffic.

## Our Lord's Candle[2]

*Yucca whipplei*

Flower stalks can reach 12'+ in height, covered with creamy white blossoms. Plant dies after blooming; new plants come from seeds or offsets. 2-3'h x 2-4'w

## Pacific Sedum[1]

*Sedum spathulefolium*

Attractive circular greenish leaves form rosettes with bright springtime yellow flowers. Does very well in rock gardens or containers. 4"h x 1'w

## Chalk Dudleya[8]

*Dudleya pulverulenta*

Base rosette of thick, chalky, gray leaves forms spike of red flowers in spring. Prefers good drainage and does well in rocky areas. 12"h x 12-18"w

## Parry's Nolina[2]

*Nolina parryi*

This plant is native to Southern California deserts and similar to *Yucca whipplei*. Long grass-like leaves form a nice mound and spring flowers are creamy white. Very drought tolerant. 4-5'h x 3-5'w

# Cacti

Including cacti in your landscape plan will add year-round interest and help conserve water. Pocket gardens of these water efficient stars are perfect for those hard to irrigate spots. The following species produce beautiful blossoms.

## Showy Stonecrop[29]

*Sedum spectabilis*

Perennial with showy foliage and late summer flowers of pink, red or white. Prefers sandy, poor soil that drains well and requires moderate irrigation. Grows in upright clump, best in groups to form tall ground cover or small hedge. 1-2'h x 1'w

## Beavertail Cactus[33]

*Opuntia basilaris*

A favorite for home gardens due to smaller size and large showy bright pink flowers. Prefers sun, little to no water, and soils that drain well. 2-4'h x 3-4'w

## Mojave Mound/Claret Cup Cactus[12]

*Echinocereus triglochidiatus*

Popular in gardens because of its small size and long-lasting, generous orange-red blooms. Creates a dense clump that can spread to a 3' circle. Little to no water required. 8"h x 18"w

## Hen and Chickens[29]

*Sempervivum tectorum*

Clusters spread to form clumps up to 2' wide. Red or reddish brown blossoms on erect stems. A variety of colored leafed plants are available. 2-5"h x 2-5"w

# Pond and Water Gardens

Even in our naturally arid area, ponds and water gardens can be designed to use California natives and will attract birds and other wildlife to your yard. These are some examples to use in a pond or nearby.

## Common Monkeyflower[1]

*Mimulus guttatus*

This plant grows naturally along streams and forms mats on still water. Large yellow flowers bloom throughout the growing season. 1-3'h x 1-3'w

## Spreading Rush[10]

*Juncas patens*

Features include strong, erect blue-green foliage with delicate brown blossoms in the spring. Does best in boggy situations. 2½'h x 3'w

## Mosquito Fern[1]

*Azolla filiculoides*

A very tiny native floating fern with reddish green ruffled leaves, this grows densely on the surface of water and discourages mosquitoes from breeding. 1"h x 2"w

## Scarlet/Western Columbine[11]

*Aquilegia formosa*

Interestingly shaped scarlet and yellow flowers on tall stems above delicate foliage, prefers moist soils (not water logged or submerged). Reseeds readily. 2½'h x 2'w

# Plants for Poolside

Plants near a pool or pond should be almost litter-free, have smooth branches, foliage, and flowers, and not be favorites of stinging insects. Here's a drought-tolerant selection that would enhance any landscape, with or without a water feature nearby.

## Red Yucca[34]

*Hesperaloe parviflora*

A native of Texas and New Mexico which produces tall stalks with rose red to bright red flowers from late spring through summer. Heat tolerant and excellent in a container. 3-4'h x 3-4'w

## California Evening-Primrose[12]

*Oenothera californica ssp. avita*

This perennial tolerates rough places with a tendency to invade. Best if kept in contained area with little irrigation. Attractive white to pink blossoms in summer. 2'h x 3'w

## Island Bush Poppy[1]

*Dendromecon harfordii*

A bushy shrub with oval gray foliage and bright yellow flowers spring to summer. Prune to shape after bloom. 6-15'h x 12'w

## Bearberry[25]

*Arctostaphylos uva-ursi*

A popular ground cover with dense bright green leathery foliage and light pink flowers; foliage turns to red or purple in winter. Slow to spread. 1'h x 3'w

# Plants for Paths and Lawn Substitutes

These hearty plants are drought-tolerant and withstand light to moderate foot traffic. Add variety to your landscape with their foliage textures and colors and save on lawn maintenance and irrigation costs.

## Dymondia Silver Carpet[20]

*Dymondia margareta*

A ground cover with light gray foliage, yellow summer blooms and deeply rooted. Tolerates light foot traffic. Good for use between stepping stones. 2-3"h x 20"w

## Creeping Wire Vine[20]

*Muehlenbeckia nana*

This plant spreads by rhizomes to create dense mounds with tiny leaves. It can be mowed yearly and tolerates poor soil and wind. 2"-1'h x 1'w

## Red Creeping Thyme[20]

*Thymus serpyllum*

A small member of the mint family, this plant has soft and fragrant foliage underfoot and dark green leaves with reddish flowers in summer. Likes well-drained soil. Can be cut back. 3"h x 3'w

## Woolly Thyme[20]

*Thymus lanuginosus*

Wooly gray foliage develops flat mats with pink flowers. Prefers infrequent sun to partial shade. 2-3"h x 3'w

# Replace Your Lawn

To create a Southern California meadow, consider using a variety of ground covers, shrubs, small trees, and grasses with attractive stones or stumps and a winding path. You will reduce your water use and maintenance costs and you'll see more butterflies and birds.

## Creeping Sage[11]

*Salvia sonomensis*

Native to the California coast range foothills and Sierra Nevada, it it's a mat-forming creeper, evergreen with narrow leaves and small lavender-blue flowers. Needs excellent drainage and gritty soil. 8-12"h x 3-4'w

## Purple Needle Grass[28]

*Nassella pulchra*

This is the classic native California bunch grass. Deep green leaves; purple seed heads age to a silvery color. 3'h x 2'w

## Common Yarrow[27]

*Achillea millefolium*

This erect plant has narrow gray-green leaves with tiny flat-topped white flower clusters. Spreads by underground runners. Cut back after blooms. 3'h x 1-2'w

## Western Blue Flax[1]

*Linum lewisii*

A small perennial with attractive blooms of 1" blue-white flowers that cover plant in spring; interesting texture. Cut back after blooming to keep compact. Easy to grow from seed. 1-2'h x 1-2'w

# Fragrant Plants

Fragrance is just one of the pleasant benefits of having a garden. Oils in the leaves, stems or petals are responsible for what we smell. Warm air and moisture enhance a plant's fragrance, but even with the hot, dry weather often experienced in local summer, a fragrant garden can still be a treat for the nose. Fragrant plants in containers or beneath a window will provide a sweet or spicy scent that can drift into the house. These four are some of the more unusual choices and are also suitable for the water-efficient landscape.

## Bush Anemone[1]

*Carpenteria californica*

This evergreen shrub has shiny dark leaves and pleasantly fragrant white flowers with golden-yellow stamens, 1.5-3" in size, from May to August. Resistant to oak root fungus, this plant does well in dry, shady conditions. Prune after flowering to restrain growth or shape. 6'h x 5'w

## Western Pennyroyal[1]

*Monardella odoratissima*

Bearing beautiful white to purple pincushion flowers and evergreen slender leaves that have a strong mint-like fragrance, this plant is often visited by bees and butterflies. Does best in the shade, with fairly rich soil and garden watering. Should be cut back regularly to maintain shape. 2-3'h x 2-3'w

## Western Azalea[1]

*Rhododendron occidentale*

This deciduous shrub prefers shade and an acidic soil. Blooms from May to June with very fragrant showy funnel-shaped flowers in clusters, with colors varying from white to pinkish white to carmine rose markings. 6-10'h x 4-8'w

## Mock Orange[1]

*Philadelphus lewisii*

Satiny, white fragrant flowers, nearly 2" across, cover this deciduous shrub from June to July. Grows in an erect and arching style. Prefers moist soils. 8-10'h x 6-10'w

# Hedges, Screens, Backgrounds

Garden hedges, either clipped into trimmed living walls or left more informal, add interest to any landscape. These attractive waterwise shrubs will help define a boundary, create a screen, present a background for the rest of your garden, and save on water needs.

## California Flannelbush[1]

*Fremontodendron californicum*

Yellow flowers create an attractive display from May to June as flowers bloom all at once. Leathery leaves are dark green above, fuzzy beneath. This shrub needs good drainage, and hillside planting is the best with staking when young. Needs no dry-season watering. 10-20'h x 20-25'w

## Toyon[3]

*Heteromeles arbutifolia*

This shrub benefits from trimming to keep its form. Thick, leathery leaves are a glossy green. Small clusters of white flowers bloom from June to July. Birds are attracted to the clusters of bright red berries from November to January. Drought tolerant, but looks better with periodic watering. 8-20'h x 20'w

## Hollyleaf Cherry[1]

*Prunus ilicifolia*

The mature foliage of this shrub is a deep, rich green that resembles holly leaves and contrasts with new leaves that are a light green. Creamy white flower spikes appear in March and bear colorful edible fruits that attract birds and wildlife. Does best in coarse, well-drained soils and requires no summer irrigation in normal rainfall years once it is established. 3-20'h x 10'w

## Coast Silktassel[1]

*Garrya elliptica*

An excellent foliage plant, this shrub is dense with elliptical, wavy-edged leaves, dark green above, gray and woolly beneath. Clustered flower tassels bloom on both male and female plants from December to February. Both plants must be present to produce grapelike clusters of purple fruit from June to September. Does best with some summer watering. 20'h x 15'w

# Manzanitas

This group of native woody plants, with interesting red bark and urn-shaped flowers, is a gardener's favorite. Making up a major portion of the chaparral hillsides, they are excellent choices for water-efficient landscapes. Many varieties are available ranging from groundcover to large shrubs and small trees.

## Bigberry Manzanita[1]

*Arctostaphylos glauca*

An excellent slope stabilizer, this shrub has large light pink blossoms in late winter to early spring and is accented by deep red twisted bark. Attractive berries follow. 8-12'h x 8-12'w

## Island Manzanita[12]

*Arctostaphylos insularis*

Often treelike, with cinnamon brown bark and broad bright green leaves, this plant has white flowers in loose clusters. Prefers well-drained soil. 3-8'h x 5-8'w

## Bearberry or Kinnikinnick[2]

*Arctostaphylos uva-ursi*

A natural for gardens with its dense, low mounds or mats that trail over rocks and walls. Slow growing, the young bark is reddish and flowers are light pink. 1'h x 2-3'w

## Common Manzanita[1]

*Arctostaphylos manzanita*

An interesting plant, this has crooked branching limbs, with smooth purplish-red bark and small green oval leaves. Generous clusters of white flowers are followed by white fruit that turns red. 6-20'h x 4-10'w

# Fruits and Berries

Plants that produce colorful fruits and berries add variety to your landscape and often are attractive to wild birds. The selections below are also suitable for hedges if kept trimmed, border backgrounds, and are drought tolerant.

## Toyon[19]

*Heteromeles arbutifolia*

This shrub benefits from trimming to keep its form. Thick, leathery leaves are a glossy green. Small clusters of white flowers bloom from June to July. Birds are attracted to the clusters of bright red berries from November to January. Drought tolerant, but looks better with periodic watering. 8-20'h x 20'w

## Chaparral Honeysuckle[33]

*Lonicera subspicata johnstonii*

A native evergreen perennial that generally looks good all the time. Clusters of creamy yellow flowers appear in spring, followed by yellowish berries that attract birds. 2-5'h x 8-10'w

## Mexican Elderberry[19]

*Sambucus mexicana*

This plant can grow into a large deciduous tree. White clusters of flowers in the summer turn into purple berries. Attractive to many bird species. 8-25'h x 10'w

## Golden Currant[14]

*Ribes aureum*

A semi-deciduous shrub that produces bright yellow flowers winter through spring, followed by yellow, orange, and red currants. 4-8'h x 7'w

# Climbers and Espaliers

Waterwise plants that climb or can be trained to cover a wall or trellis are useful and attractive additions to any landscape. These selections are strong enough to climb and still be guided into position. With proper pruning and shaping, they will provide interesting color and texture backgrounds.

## Hollyleaf Cherry[1]

*Prunus ilicifolia*

Growing at a moderate rate, this tall shrub has deep green leaves 1-2" long that resemble holly. Creamy white flowers produce edible fruit attractive to wildlife. Grows in well-drained poor soils and once established requires no irrigation in a normal rain year. 3-20'h x 10'w

## Lemonade Berry[12]

*Rhus integrifolia*

This shrub has dark, leathery leaves with delicate pink flowers. Fairly tolerant to cold temperatures, watering once a month will improve its resistance to fire. 10'h x 15'w

## California Honeysuckle[1]

*Lonicera hispidula*

A climbing shrub, this plant is native throughout most of California and up the coast to Washington. Deciduous foliage, with large pink flowers, the edible fruit is bitter but attracts birds. Able to handle cold temperatures and is not favored by deer. 4'h x 1'w

## California Wild Grape[1]

*Vitis californica*

A deciduous vine, this plant produces clusters of small edible grapes. Able to climb better with support; prefers regular irrigation (but not wet soil) and will seek out as much sun as possible. Small flowers are attractive to bees. 30'h x 1-2'w

# Showy Shrubs

If you think native and drought-tolerant shrubs are dull and boring, check out these examples that put on a showy display of blooms.

## California Flannelbush[1]

*Fremontodendron californicum*

Yellow flowers create an attractive display from May to June as flowers bloom all at once. Leathery leaves are dark green above, fuzzy beneath. This shrub needs good drainage, and hillside planting is the best with staking when young. Needs no dry-season watering. 10-20'h x 20-25'w

## Red-flowering Currant[1]

*Ribes sanguineum*

This deciduous shrub produces long drooping clusters of deep pink to red flowers in spring; blue-black fruit follows. 3-8'h x 3-8'w

## Butterfly Bush[21]

*Buddleja davidii*

A semi-evergreen shrub with tall arching branches; blooms in mid-summer with dense small, fragrant spike-like clusters. Needs good drainage and pruning to keep shape. 4-7'h x 3-5'w

## Bush Anemone[1]

*Carpenteria californica*

This California native shrub displays dark green foliage highlighted by 3" single-petaled fragrant white flowers with golden stamens. 6'h x 5'w

# Herbs in the Water Efficient Garden

The climate in our area is perfect for growing Mediterranean herbs. Perennial herbs can add color, fragrance and culinary options (using edible varieties such as these) to your garden. The following require little irrigation once established.

## Rosemary[10]

*Rosmarinus officinalis*

A tough evergreen shrub with short, narrow green leaves on woody stems with delicate blue flowers. Requires good drainage; pruning encourages new growth. 4'h x 4'w

## English Thyme[10]

*Thymus vulgaris*

An attractive plant with small, gray-green pungent leaves and white-lilac flowers in late spring. Useful as a border edging or in a container with good drainage. 1'h x 1'w

## Greek Oregano[10]

*Origanum vulgare hirtum*

A shrubby plant with slightly fuzzy gray-green leaves and tiny clusters of small flowers. Needs good drainage. 2-3'h x 1'w

## Common Sage[10]

*Salvia officinalis*

This shrubby plant with wrinkled oval leaves displays clusters of bluish flowers on spikes in the spring. Less than excellent drainage may cause root rot. 1-3'h x 1-2'w

# Winter is Planting Time

The cool wet months of winter are ideal for planting native species. Root systems can be established before the stress of summer begins. Gardeners can generally begin to reduce the amount of irrigation to new plantings by the first spring. Try these colorful species to enjoy an attractive natural landscape.

## Sticky Monkeyflower[26]

*Mimulus aurantiacus*

This high-to-medium drought-tolerant perennial has showy spring apricot-colored blossoms that attract hummingbirds. Light summer watering will extend its blooming period. 1-4'h x 3'w

## Bush Sunflower[1]

*Encelia californica*

A small deciduous shrub with loose clusters of yellow daisy-like flowers. Light summer water will extend blooming. Cut back every two years to maintain shape. 3'h x 5'w

## Chaparral Currant[3]

*Ribes malvaceum*

This medium-sized deciduous shrub has cascading clusters of fragrant pink flowers in the fall, winter, and early spring. Does best in the shade, requires very little maintenance, and light irrigation to prevent dormancy in the summer. 5-8'h x 5'w

## Creeping Mahonia[1]

*Mahonia repens*

An ideal groundcover for partial sun to full shade areas with colorful winter foliage. Does well under oak trees, requiring little to no irrigation once established. Yellow spring flowers are followed by berries that attract birds. 1'h x 3+'w

# Interesting Blossoms

Here's an array of waterwise plants with interesting blossoms. One or more of the following might catch your eye and brighten your garden. Whether featuring feathery fairy-duster tassels, orchid-like brilliance, or unusual structure, these four species are all rated as high to medium drought tolerant.

## Apache Plume[12]

*Fallugia paradoxa*

A semi-evergreen shrub with flowers resembling single white roses that are followed by large, feathery seedheads that change from green to red. Requires well-drained soil. 4-6'h x 5'w

## Desert Willow[12]

*Chilopsis linearis*

This deciduous tree or shrub develops shaggy bark and a twisting trunk with age. Spring brings fragrant trumpet-shaped blossoms in a variety of colors, that attract hummingbirds. Drops seed pods in the winter. Trim to keep shapely. 15-30'h x 10-20'w

## Matilija Poppy[1]

*Romneya coulteri*

An extremely hardy perennial that's slow to start. Once established, produces amazing "fried egg" blossoms. Spreads by underground runners. 3-5'h x 8+'w

## Western Spice Bush[1]

*Calycanthus occidentalis*

This deciduous shrub has green leaves that turn yellow in the fall. Blossoms resemble brownish-red water lilies. Both foliage and flowers are fragrant. 4-12'h x 4-12'w

# Hardy Waterwise Plants

Freezing winter temperatures may leave their mark on your landscape with dead shrubs and brown patches. As you replant, consider using one of these hardy natives that are less prone to cold weather damage. They are also water efficient and will help reduce your irrigation costs.

## Bigberry Manzanita[1]

*Arctostaphylos glauca*

This evergreen shrub has attractive deep red twisted bark. Abundant light pink flowers bloom during winter and spring. Hardy to 10 -15°F. 8-12'h x 8-12'w

## California Buckwheat[26]

*Eriogonum fasciculatum*

A small evergreen shrub with summer and fall blooms of pinkish flower clusters that turn rusty red. Attractive to butterflies and hardy to around 15°F. 3-5'h x 6'w

## Mountain Mahogany[22]

*Cercocarpus betuloides*

Extremely drought tolerant, this evergreen shrub is a good erosion controller. White flowers bloom in the spring and produce attractive seed plume. 6-20'h x 12'w

## Evergreen Currant[28]

*Ribes viburnifolium*

Evergreen shrub; fragrant dark green leaves; light pink to purplish flowers in winter and spring; suitable for under oaks; hardy to 15 – 20°F. 3-4'h x 6'w

# Native Buckwheats

These natives are related to the true buckwheat of Asia grown as food crop. As a group they range from shrubs, to mounding and matting subshrubs. With a long bloom span from summer through fall, they are a welcome addition to the "California-friendly" landscape.

## Ashyleaf Buckwheat[36]

*Eriogonum cinereum*

This can be a nice shrub when kept trimmed. Silver gray foliage is covered with white flowers in the summer. Best planted in groups, this will tolerate salt spray and is good for erosion control. 4-6'h x 4-6'w

## California Buckwheat[32]

*Eriogonum fasciculatum*

This native is an important honey plant, attractive to butterflies, and will help stabilize slopes. Forms hemispheres of growth, topped with pinkish-white blossoms in the summer that turn to rusty red in the fall. 3-5'h x 6'w

## Sulphur Buckwheat[2]

*Eriogonum umbellatum*

This plant is very drought tolerant and grows well on dry slopes with good drainage. Bright yellow flowers form in the spring above low, broad mounds of 1" green foliage. Flowers age to rust. 12"h x 3'w

## Cliff or Coast Buckwheat[32]

*Eriogonum parvifolium*

This is a low growing, spreading variety that cascades. White to pinkish flowers appear in late spring to summer above reddish green leaves. An important butterfly plant. 1-2'h x 4-6'w

# Landscape Enhancers

A turf lawn requires up to 60" of water a year. That's five feet! Save water by converting part of your lawn to "California-friendly" plants. When you reduce the amount of lawn, you'll reduce your irrigation needs, provide habitat for native birds and insects, conserve water and save money.

## Cotoneaster[10]

*Cotoneaster sp.*

Plants range from ground covers to shrubs and require little to moderate water. Attractive arching branches, fall color; red or orange berries in winter add appeal. Thrives with little to no maintenance and does well on dry slopes and in poor soil. 4"–15'h x 10"–18'w

## Desert Marigold[12]

*Baileya multiradiata*

This perennial has bright yellow flowers above gray-green foliage spring through fall. Extend blooming with periodic moisture. Attracts butterflies. Requires good drainage. 1-2'h x 1-1½'w

## Wild / Sand Strawberry[1]

*Fragaria chiloensis*

Native to Pacific coast beaches and bluffs, this perennial plant can be mowed or cut back in early spring to force new growth. Shiny green foliage turns red in the fall; white blossoms in spring with occasional fruit. 4-8"h x 1'w

## Sea Lavender[1]

*Limonium perezii*

A perennial with large leaves and clusters of tiny purplish flowers that is good for cutting and can be dried. Prefers temperatures above 25˚F and tolerates heat; needs good drainage. 3'h x 2'w

# Coyote Mints

These colorful and interesting plants are members of the mint family. They require well drained soil, have short underground rhizomes, develop clumps or small thickets of shoots, and range from ground cover size to 2" tall. Their predominant feature is their powerful aroma, a blend of sweet and minty to more pungent. Plants can often be purchased at native plant sales, botanic gardens, and specialized nurseries.

## Yellow Mountainbalm[1]

*Monardella nana*

A low-lying, often matting plant, the stems are greenish white. Flowers are spidery white to light pink, about 1" long, and bloom from April to July. 6"h

## Coyote Mint[1]

*Monardella villosa*

A plant with light purple 1" flowers from June to August. Foliage is furry gray-green and butterflies are attracted to the plant. Likes sun to partial shade. 1-2'h x 1'w

## Serpentine Monardella[35]

*Monardella purpurea*

Blunt-tipped leaves are up to 1" long and dark green. Flowers are reddish purple and bloom from mid-summer to early fall. 4" – 12"h

## Western Pennyroyal[1]

*Monardella odoratissima*

Beautiful purple flowers attract butterflies and bees; very minty fragrance. Cut back regularly to maintain shape. 2-3'h x 2-3'w

# Variety of Lupines

Plan ahead for a spring show of beauty by planting lupines. Attractive to butterflies, lupines come in many varieties, some growing as carpets of annuals and others as garden perennials or shrubs. Trimming will keep plants sturdy and compact. The foliage and blossom colors will delight any gardener.

## Silver Bush Lupine[4]

*Lupinus albifrons*

One of the most variable lupines, often a shrub; narrow leaflets covered with silky hairs; purple-blue to reddish violet flowers on tall stems, often with sweet fragrance. 6-4'h x 4'w

## Yellow Bush Lupine[3]

*Lupinus arboreus*

Shrubby with yellow flowers (blue flower types available), and lemony fragrance; grows erect, stem stout and gnarled; leaflets generally deep to pale green above and light green to gray beneath. 5'h x 4'w

## Sky Lupine[1]

*Lupinus nanus*

Easy to grow from seed sown in the fall or winter, this annual bears blue flowers marked with white. Self sows if there is little competition; good for bare slopes and banks. 8-24"h x 9-12"w

## Broad-leaf Lupine[1]

*Lupinus latifolius*

Perennial with large broad grey leaves and showy medium blue-purple flowers. 4'h x 4'w

# Summer Color

Have you shied away from drought tolerant native plants in the belief they become less attractive in the warmer months? Here are a few suggestions that will bring sprays of color to your landscaping, save on irrigation costs and attract wildlife. That's a three-for-one bonus!

## Mexican Whorled Milkweed[2]

*Asclepias fascicularis*

Spreading semi-deciduous perennial, commonly found in dry grassy meadows, with linear foliage. Flowers are greenish white or purple, blooming from June to September. Interesting seed pods open and spill out hundreds of fine white hairs. Provides an important food source plant for Monarch butterflies. Prefers sun to partial sun exposure. 3'h x 3'w

## St. Catherine's Lace[1]

*Eriogonum giganteum*

Native to San Clemente and Santa Catalina Islands, displays freely branching stems, with silver to grayish-white, broadly oval leaves, with magnificent white blooms throughout the summer. Blossoms are actually tiny, but grow in a cluster on long stems. Attractive to butterflies and in dry arrangements. Prefers sun exposure and well-drained, loose, gravelly soil. Useful to cover dry banks, among rocks. 6'h x 6'w

## Heart-leaf Penstemon[1]

*Keckiella cordifolia*

Deciduous perennial vining shrub, with spiked clusters of orange red tubular flowers on arching branches. Blooms from March to August. An important hummingbird plant, commonly found in canyons and hillsides, it prefers sun to partial sun exposure. Will remain evergreen with summer irrigation. 5'h x 8'w

## Woolly Blue Curls[3]

*Trichostoma lanatum*

Many branched, tidy plant with linear leaves, pungently aromatic when bruised. Blossoms are striking purple spikes, attractive to hummingbirds, showing from March to August, and longer if old flower stems are cut back. Flowers have a wooly appearance, with blue, purple, or whitish hairs. Requires excellent drainage and sunny hillside exposures. Does not like summer irrigation. 4'h x 4'w

# Weeds: Plants Out of Place

Invasive plants out-compete native species for resources. They change the landscape, the protections it provides, and can be a nuisance, or worse. Be watchful that these invasives don't begin to inhabit your landscape. (For other California invasive plants, go to www.cal-ipc.org)

## Yellow Star Thistle[18]

*Centaurea solstitialis*

This relatively new arrival in the area is found in dry fields, along roads and trails, and other disturbed areas. An annual, with bright yellow disk flowers, that blooms May to October. Spikes ¼-¾" long grow below the flowers and are painful when encountered. Horses that feed on this plant develop an incurable and fatal brain disease. 1-2'h x 6"w

## Tocalote - Maltese Star Thistle[2]

*Centaurea melitensis*

A smaller cousin to Yellow Star Thistle, this common annual is found in dry fields, disturbed areas, and along trails and roads. Disk flowers (some are yellow), bloom May to June. Branched spines, up to 3/8" long, are purple or brown tinged. 1-2'h x 6"w

## Black Mustard[1]

*Brassica nigra*

An extremely common annual found growing in meadows, disturbed areas, and along trails and roads. Bright yellow petals grow on top of erect branching stems, blooming February to July. 2-8'h

## Tree-of-Heaven[1]

*Ailanthus alitssima*

A native of China, this deciduous tree grows rapidly, self-seeding and producing new plants with suckers. Leaves grow from 1-3' long. Does very well under adverse conditions. 50'h x 50'w

## Common - Scientific Names

(NN = Non-California Native)

| Arctostaphylos insularis | Island Manzanita |
| Arctostaphylos manzanita | Common Manzanita |
| Arctostaphylos uva-ursi | Bearberry |
| Asclepias fascicularis | Mexican Whorled Milkweed |
| Azolla filiculoides (NN) | Mosquito Fern |
| Baccharis pilularis | Coyote Bush |
| Baileya multiradiata | Desert Marigold |
| Berberis aquilifolium (NN) | Oregon Grape |
| Brodiaea elegans | Harvest Brodiaea |
| Buddleja davidii (NN) | Butterfly Bush |
| Calliandra eriophylla (NN) | Fairy Duster |
| Calochortus venustus | White Mariposa Lily |
| Calycanthus occidentalis | Western Spice Bush |
| Camissonia cheiranthefolia | Beach Suncups |
| Carpenteria californica | Bush Anemone |
| Ceanothus impressus (cultivars) | Santa Barbara Ceanothus |
| Cercis occidentalis | California Redbud |
| Cercocarpus betuloides | Mountain Mahogany |
| Chilopsis linearis | Desert Willow |
| Cistus spp (NN) | Rockrose |
| Cotoneaster spp (NN) | Cotoneaster |
| Dalea spp (greggi) (NN) | Desert Beauty/Indigo Bush |
| Delphinium cardinale | Scarlet Larkspur |
| Dendromecon harfordii | Island Bush Poppy |
| Dendromecon rigida | Tree Poppy |
| Dudleya cymosa | Canyon Live-Forever |
| Dudleya pulverulenta | Chalk Dudleya |
| Dymondia margareta (NN) | Dymondia Silver Carpet |
| Echinocereus triglochidiatus | Mojave Mound / Claret Cup Cactus |
| Elymus condensatus | Giant Wild Rye |
| Encelia californica | Bush Sunflower |
| Erigeron glaucus | Seaside Daisy / Beach Aster |
| Eriogonum cinereum | Ashyleaf Buckwheat |
| Eriogonum fasciculatum | California Buckwheat |
| Eriogonum grande rubescens | Red Buckwheat |
| Eriogonum giganteum | St. Catherine's Lace |
| Eriogonum parvifolium | Cliff / Coast Buckwheat |
| Eriogonum umbellatum | Sulphur Buckwheat |
| Eriophyllum confertiflorum | Golden Yarrow |
| Eschscholzia californica | California Poppy |
| Fallugia paradoxa (NN) | Apache Plume |
| Festuca ovina (glauca) (NN) | Sheep Fescue (Blue) |

## Scientific - Common Names
(NN = Non-California Native) *continued*

| | |
|---|---|
| Fragaria chiloensis | Wild/Sand Strawberry |
| Fremontodendron californicum | California Flannelbush |
| Galvezia speciosa | Island Bush Snapdragon |
| Garrya elliptica | Coast Silktassel |
| Gilia capitata | Globe Gilia |
| Hesperaloe parviflora | Red Yucca |
| Heteromeles arbutiflia | Toyon |
| Heuchera maxima | Alum Root Hybrids |
| Heuchera (sanguina) | Alum Root/Coral Bells |
| Iris douglasiana | Douglas Iris |
| Juncas patens | Spreading Rush |
| Keckiella cordifolia | Heart-leaf Penstemon |
| Kniphofia uvaria (NN) | Red-Hot Poker |
| Lavandula angustifolia (NN) | English Lavender |
| Lavandula dentate (NN) | French Lavender |
| Lavandula heterophylla (NN) | Sweet Lavender |
| Lavandula stoechas (NN) | Spanish Lavener |
| Layia platyglossa | Tidy Tips |
| Lilium pardalimum | Leopard Lily |
| Limonium perezii (NN) | Sea Lavender / Statice |
| Linum lewisii | Western Blue Flax |
| Lonicera hispidula | California Honeysuckle |
| Lonicera involucrata | Twinberry Honeysuckle |
| Lonicera subspicata johnstonii | Chaparral Honeysuckle |
| Lupinus albifrons | Silver Bush Lupine |
| Lupinus arboreus | Yellow Bush Lupin |
| Lupinus latifolius | Bigleaf Lupine |
| Lupinus nanus | Sky Lupine |
| Mahonia repens | Creeping Mahonia |
| Malacothamnus fasciculatus | Mesa Bushmallow |
| Mimulus aurantiacus | Sticky Monkeyflower |
| Mimulus guttatus | Common Monkeyflower |
| Monardella nana | Yellow Mountainbalm |
| Monardella odoratissima | Western Pennyroyal |
| Monardella purpurea | Serpentine Monardella |
| Monardella villosa | Coyote Mint |
| Muehlenbeckia nana (axillaris) (NN) | Creeping Wire Vine |
| Muhlenbergia rigens | Deergrass (Dwarf Mullee) |
| Myrica californica | Pacific Wax Myrtle |
| Nassella pulchra | Purple Needle Grass |
| Nolina parryi | Parry's Nolina |
| Oenothera californica | California Evening-Primose |
| Opuntia basilaris | Beavertail Cactus |
| Origanum vulgare hirtum (NN) | Greek Oregano |
| Penstemon centranthifolius | Scarlet Bugler |
| Penstemon clevelandii | Cleveland's Beardtongue |
| Penstemon eatonii | Firecracker Penstemon |
| Penstemon floridus | Panamint Beard Penstemon |
| Penstemon palmeri | Palmer's Penstemon |
| Penstemon spectabilis | Showy Penstemon |
| Philadelphus lewisii | Mock Orange |
| Platanus racemosa | California Sycamore |
| Populus fremontii | Fremont's Cottonwood |
| Potentilla tabernaemontanii (NN) | Spring Cinquefoil |
| Prunus ilicifolia | Hollyleaf Cherry |
| Quercus agrifolia | Coast Live Oak |
| Quercus beberidifolia | Scrub Oak |
| Quercus lobata | Valley Oak |
| Quercus wislizenii | Interior Live Oak |
| Rhododendron occidentale | Western Azalea |
| Rhus integrifolia | Lemonade Berry |
| Ribes aureum | Golden Currant |
| Ribes malvaceum | Chaparral Currant |
| Ribes sanguineum | Red-flowering Currant |
| Ribes sanguineum var. glutinosum | Pink-flowering Currant |
| Ribes viburnifolium | Evergreen Currant |
| Romneya coulteri | Matilija Poppy |
| Rosmarinus officinalis (NN) | Rosemary |
| Salvia clevelandii | Cleveland Sage |
| Salvia leucantha (NN) | Mexican Bush Sage |
| Salvia leucophylla | Purple Sage |
| Salvia mellifera 'Tera Seca' | Black Sage (creeping) |
| Salvia officinalis (NN) | Common Sage |
| Salvia sonomensis | Creeping Sage |
| Salvia spathacea | Hummingbird Sage |
| Sambucus mexicana | Mexican Elderberry |
| Sedum spathulefolium | Pacific Sedum Stonecrop |
| Sedum spectabilis | Showy Stonecrop |
| Sempervivum tectorum | Hen and Chickens |
| Sisyrinchium bellum | Blue-eyed Grass |
| Sphaeralcea ambigua | Desert/Apricot Mallow |
| Thymus lanuginosus (NN) | Woolly Thyme |
| Thymus serpyllum (NN) | Red Creeping Thyme |
| Thymus vulgaris (NN) | English Thyme |
| Trichostoma lanatum | Woolly Bluecurls |
| Tulbaghia violacea (NN) | Society Garlic |
| Umbellularia californica | California Bay Laurel |
| Vitis californica | California Wild Grape |
| Yucca whipplei | Our Lord's Candle |
| Zauschneria californica | California Fuchsia |

Seaside Daisy[1]

# Suitability Lists

NOTE: The plants listed here may or may not be included in this booklet. Please check other reference guides for more descriptions if not represented.

**Erosion Control** – These plants have strong root systems. However, many should not be planted near structures as they produce large fuel supplies for fires.

| | | |
|---|---|---|
| | Alum Root | *Heuchera sp.* |
| | Bigberry Manzanita | *Arctostaphylos glauca* |
| | Big-pod Ceanothus | *Ceanothus megacarpus* |
| | Black Sage | *Salvia mellifera* |
| | Blue-eyed Grass | *Sisyrinchium bellum* |
| | Buckwheat | *Eriogonum sp.* |
| | California Bay | *Umbellularia californica* |
| | California Brome | *Bromus carinatus* |
| | California Fuchsia | *Zauschneria californica* |
| | California Live Oak | *Quercus agrifolia* |
| | California Sagebrush | *Artemisia californica* |
| | California Wild Strawberry | *Fragaria californica* |
| | California Walnut | *Juglans californica* |
| | Chamise | *Adenostema fasciculatum* |
| | Coyote Brush | *Baccharis pilularis* |
| | Creeping Sage | *Salvia sonomensis* |
| | Deergrass | *Muhlenbergia rigens* |
| | Eastwood Manzanita | *Arctostaphylos glandulosa* |
| | Elderberry | *Sambuscus mexicana* |
| | Evergreen Currant | *Ribes viburnifolium* |
| | Flannelbush | *Fremontodendron sp.* |
| | Fremont Cottonwood | *Populus fremontii* |
| | Giant Wild Rye | *Elymus condersatus* |
| | Golden Yarrow | *Eriophyllum lanatum* |
| | Greenbark Ceanothus | *Ceanothus spinosus* |
| | Holly-leaf Cherry | *Prunus ilicifolia* |
| | Hollyleaf Redberry | *Rhamnus ilicifolia* |
| | Honeysuckle | *Lonicera sp.* |
| | Laurel Sumac | *Malosma laurina* |
| | Lemonadeberry | *Rhus integrifolia* |
| | Mesa Bush Mallow | *Malacothamnus fasciculatus* |
| | Mountain Mahogany | *Cercocarpus betuloides* |
| | Our Lord's Candle | *Yucca whipplei* |
| | Prickly Phlox | *Leptodactylon californica* |
| | Purple Needlegrass | *Nassella pulchra* |
| | Purple Sage | *Salvia leucophylla* |
| | Rockrose | *Cistus sp.* |
| | Stonecrop | *Sedum sp.* |
| | Sugarbush | *Rhus ovata* |
| | Toyon | *Heteromeles arbutifolia* |
| | Tree Mallow | *Lavatera assurgentiflora* |
| | Valley Oak | *Quercus lobata* |
| | Western Redbud | *Cercis occidentalis* |
| | White Sage | *Salvia apiana* |
| | Yellow-eyed Grass | *Sisyrinchium californicum* |

**Deer Resistant** – Deer do not seem to like plants with sticky, rough or fuzzy textures, spiny stems or fragrant leaves.

| | | |
|---|---|---|
| | Agave | *Agave sp.* |
| | Arizona Ash | *Fraxinus velutina* |
| | Big-Leaf Maple | *Acer macrophyllum* |
| | Blue-eyed Grass | *Sisyrinchium bellum* |
| | Bush Anenome | *Carpenteria californica* |
| | California Bay | *Umbellularia californica* |
| | California Live Oak | *Quercus agrifolia* |
| | California Poppy | *Eschscholzia californica* |
| | California Sycamore | *Plantanus racemosa* |
| | California Wild Strawberry | *Fragaria californica* |
| | Catclaw | *Acacia gregii* |
| | Coyote Brush | *Baccharis pilularis* |
| | Dusty Miller | *Senecio cineraria* |
| | Elderberry | *Sambuscus mexicana* |
| | False Indigo | *Baptisia sp.* |
| | Flannel Bush | *Fremontodendron sp.* |
| | Golden Currant | *Ribes aureum* |
| | Iris | *Iris sp.* |
| | Lavender | *Lavendula sp.* |
| | Lobelia | *Lobelia ssp.* |
| | Matilija Poppy | *Romneya coulteri* |
| | Mexican Marigold | *Tagetes lemonii* |
| | Milkweed | *Asclepias sp.* |
| | Nolina | *Nolina sp.* |
| | Salvia | *Salvia sp.* |
| | Sea Pink | *Armeria sp.* |
| | Seaside Daisy | *Erigeron glaucus* |
| | Sheep Fescue | *Festuca trachyphylla* |
| | Spicebush | *Calycanthus occidentalis* |
| | Sugarbush | *Rhus ovata* |
| | Valley Oak | *Quercus lobata* |
| | Western Redbud | *Cercis occidentalis* |
| | Wild Lilac | *Ceanothus sp.* |
| | Yarrow | *Achillea sp.* |
| | Yerba Buena | *Satureja douglasii* |
| | Yucca | *Yucca sp.* |

**Desert Natives** – These require well-drained soils and very little irrigation.

| | | |
|---|---|---|
| | Bladderpod | *Isomeris arborea* |
| | Blue Grama | *Boutelona gracilis* |
| | Brittlebush | *Encelia farinose* |
| | Catclaw | *Acacia gregii* |
| | Desert Agave | *Agave deserti* |
| | Desert Mallow | *Sphaeralcea ambigua* |
| | Desert Marigold | *Baileya multiradiata* |
| | Desert Willow | *Chilopsis linearis* |
| | Live-Forever | *Dudleya sp.* |
| | Mexican Palo Verde | *Parkensonia aculeate* |
| | Palo Verde | *Cercidium floridum* |
| | Stonecrop | *Sedum sp.* |
| | Yucca | *Yucca sp.* |

**Water Tolerant –** These plants will look nicer with regular irrigation.

| | | |
|---|---|---|
| | California Hibiscus | *Hibiscus californica* |
| | Canyon Sunflower | *Venegassia carpespiodes* |
| | Cottonwood | *Populus sp.* |
| | Deergrass | *Muhlenbergia reigens* |
| | Giant Wild Rye | *Elymus condensatus* |
| | Gumplant | *Grindelia stricta* |
| | Melic Grass | *Melica imperfecta* |
| | Mock Orange | *Philadelphus lewisii* |
| | Mugwort | *Artemisia douglasiana* |
| | Oregon Ash | *Fraxinus latifolius* |
| | Spicebush | *Calycanthus occidentalis* |
| | Twinberry | *Lonicera involucrate* |
| | White Alder | *Alnus rhombifolia* |
| | Yellow-eyed Grass | *Sisyrinchium californicum* |

**Fragrant –** Many native plants exude strong fragrances, some mild and pleasant, others pungent.

| | | |
|---|---|---|
| | Bladderpod | *Isomeris arborea* |
| | Broad-leaf Lupine | *Lupinus latifolius parishii* |
| | Bush Anenome | *Carpenteria californica* |
| | California Bay Laurel | *Umbellularia californica* |
| | Coyote Mint | *Monardella ssp.* |
| | Currant/Gooseberry | *Ribes sp.* |
| | Hedge-nettle | *Stachy ssp.* |
| | Lavender | *Lavendula sp.* |
| | Lavender Cotton | *Santolina virens* |
| | Meadow Rue | *Thalictrum polycarpum* |
| | Mexican Bush Marigold | *Tagetes lemonii* |
| | Mock Orange | *Philadelphus lewisii* |
| | Oregano of the Highway | *Monarda menthaefolia* |
| | Pitcher Sage | *Lepechinia sp.* |
| | Sage | *Salvia* |
| | Sagebrush | *Artemisia sp.* |
| | Spicebush | *Calycanthus occidentalis* |
| | Tule Mint | *Menth arvensis* |
| | Wax Myrtle | *Myrica californica* |
| | Western Azalea | *Rhododendron occidentale* |
| | Wild Lilac | *Ceanothus sp.* |
| | Woolly Blue Curls | *Trichostema lanatum* |
| | Yerba Buena | *Satureja douglasii* |
| | Yerba Mansa | *Anemopsis californica* |

**Under Oak Trees -** These plants tolerate shade and thrive in dry conditions essential for oak tree survival in dry months.

| | | |
|---|---|---|
| | Barberry | *Mahonia aquifolium* |
| | Bush Anenome | *Carpenteria californica* |
| | Bush Snapdragon | *Galvezia juncea* |
| | Coffeeberry | *Rhammus californica* |
| | Creeping Barberry | *Mahonia repens* |
| | Currant/Gooseberry | *Ribes sp.* |
| | Holly-leaf Cherry | *Prunus ilicifolia* |
| | Hummingbird Sage | *Salvia spathacea* |
| | Island Alum Root | *Heuchera maxima* |

**Water Gardens –** These plants can be used in and around ponds or in areas that receive regular irrigation.

| | | |
|---|---|---|
| | California Wild Rose | *Rosa californica* |
| | Columbine | *Aquilegia formosa* |
| | Hooker's Evening Primrose | *Oenothera hookeri* |
| | Lobelia | *Lobelia ssp.* |
| | Oregano of the Highway | *Monarda menthaefolia* |
| | Reed | *Juncus sp.* |
| | Scarlet Monkeyflower | *Mimulus cardinalis* |
| | Tufted Hairgrass | *Deschampsia caespitosa* |
| | Tule Mint | *Mentha arvensis* |
| | White Hedge-Nettle | *Stachys albens* |
| | Willow | *Salix sp.* |
| | Yellow-Stream Monkeyflower | *Mimulus guttatus* |
| | Yerba Buena | *Satureja douglasii* |
| | Yerba mansa | *Anemopsis californica* |
| | Yarrow | *Achillea sp.* |

**Fire Resistant –** These plants are fire resistant due to physiological characteristics (FR), due to growth habits, or are succulents (S) which are considered fire retardant.

| | | |
|---|---|---|
| | Agave (S) | *Agave sp.* |
| | Alum Root | *Heuchera sp.* |
| | Beach Suncups | *Camissonia cheiranthifolia* |
| | Bladderpod (FR) | *Isomeris arborea* |
| | Blue Flax | *Linum lewisii* |
| | Blue-eyed Grass | *Sisyrinchium bellum* |
| | California Fuchsia | *Zauschneria californica* |
| | Carmel Creeper | *Ceanothus griseus horizontalis* |
| | Coast Buckwheat | *Eriogonum parvifolium* |
| | Columbine | *Aquilegia formosa* |
| | Conejo Buckwheat | *Eriogonum crocatum* |
| | Coyote Brush (FR) | *Baccharis pilularis* |
| | Creeping Barberry | *Mahonia repens* |
| | Creeping Sage | *Salvia sonomensis* |
| | Evergreen Currant | *Ribes viburnifolium* |
| | Four-winged Saltbush (FR) | *Atriplex canescens* |
| | Golden Yarrow | *Eriophyllum lanatum* |
| | Guadalupe Island Rock Daisy (FR) | *Perityle incana* |
| | Hummingbird Sage | *Salvia spathacea* |
| | Iris | *Iris sp.* |
| | Live-Forever (S) | *Dudleya sp.* |
| | Lupine | *Lupinus sp.* |
| | Matilija Poppy (FR) | *Romneya coulteri* |
| | Meadow Rue | *Thalictrum polycarpum* |
| | Monkeyflower | *Mimulus sp.* |
| | Nolina (S) | *Nolina sp.* |
| | Penstemon | *Penstemon sp.* |
| | Quailbush (FR) | *Atriplex lentiformis* |
| | Red Bearberry | *Arctostaphylos uva-ursi* |
| | Red Buckwheat | *Eriogonum grande rubescens* |
| | Scarlet Larkspur | *Delphinium cardinale* |
| | Sea Dahlia | *Coreopsis maitima* |
| | Seaside Daisy | *Erigeron glaucus* |
| | Stonecrop (S) | *Sedum sp.* |
| | Tree Mallow | *Lavatera assurgentiflora* |
| | Yarrow | *Achillea sp.* |
| | Yellow-eyed Grass | *Sisyrinchium californicum* |
| | Yucca | *Yucca sp.* |

**Attract Birds** – These plants provide berries, foliage, fruit, and nectar.

| | | |
|---|---|---|
| | Alum Roots | *Heuchera sp.* |
| | Bee Balm | *Monarda sp.* |
| | Buckwheat | *Eriogonum sp.* |
| | Butterfly Bush | *Buddleja davidii* |
| | Butterfly Weed | *Asclepias tuberose* |
| | California Fuchsia | *Zauschneria californica* |
| | Clarkia | *Clarkia sp.* |
| | Columbine | *Aquilegia sp.* |
| | Currant/Gooseberry | *Ribes sp.* |
| | Elderberry | *Sambucus mexicana* |
| | Flowering Maple | *Abutilon sp.* |
| | Honeysuckle | *Lonicera sp.* |
| | Lobelia | *Lobelia sp.* |
| | Lupine | *Lupinus sp.* |
| | Monkeyflower | *Mimulus sp.* |
| | Penstemon | *Penstemon sp.* |
| | Sage | *Salvia sp.* |
| | Toyon | *Heteromeles arbutifolia* |
| | Western Redbud | *Cercis occidentalis* |

**Hummingbird Plants** – These plants provide nectar for hummingbirds. Non-nectar feeding birds use them for nesting, cover and feed.

| | | |
|---|---|---|
| | Alum Root | *Heuchera sp.* |
| | Bladderpod | *Isomeris arborea* |
| | Bush Snapdragon | *Galvezia sp.* |
| | California Fuchsia | *Zauschneria sp.* |
| | Columbine | *Aquilegia sp.* |
| | Currant/Gooseberry | *Ribes sp.* |
| | Desert Willow | *Chilopsis linearis* |
| | Heart-leafed Penstemon | *Keckiella cordifolia* |
| | Honeysuckle | *Lonicera sp.* |
| | Larkspur | *Delphinium sp.* |
| | Lavender | *Lavendula sp.* |
| | Monkeyflower | *Mimulus sp.* |
| | Penstemon | *Penstemon sp.* |
| | Pitcher Sage | *Lepechinia sp.* |
| | Primrose | *Oenothera sp.* |
| | Sage | *Salvia sp.* |
| | Scarlet Lobelia | *Lobelia cardinalis* |
| | Tree Mallow | *Lavatera assurgentiflora* |
| | Woolly Blue Curls | *Trichostema lanatum* |

**Tolerant of Heavy Soils** – These plants will survive in heavy clay soils, depending on other variables involved.

| | | |
|---|---|---|
| | Barberry | *Mahonia sp.* |
| | Black Cottonwood | *Populus trichocarpus* |
| | Bladderpod | *Isomeris arborea* |
| | Blue-eyed Grass | *Sisyrinchium bellum* |
| | Buckwheat | *Eriogonum sp.* |
| | Bush Anenome | *Carpenteria californica* |
| | Butterfly Bush | *Asclepias fascicularis* |
| | California Rose | *Rosa californica* |
| | California Sagebrush | *Artemisia californica* |
| | California White Alder | *Alnus rhombifolia* |
| | Catalina Ironwood | *Lyonothamnus floribundus* |
| | Coast Sunflower | *Encelia californica* |
| | Coffeeberry | *Thamnus californica* |
| | Currant/Gooseberry | *Ribes sp.* |
| | Douglas Iris | *Iris douglasiana* |
| | Hollyleaf Cherry | *Prunus ilicifolia* |
| | Island Alum Root | *Heuchera maxima* |
| | Island Bush Poppy | *Dendromencon harfordii* |
| | Island Bush Snapdragon | *Galvezia speciosa* |
| | Lemonadeberry | *Rhus integrifolia* |
| | Lupine | *Lupinus sp.* |
| | Manzanita | *Arctostaphyllos sp.* |
| | Matilija Poppy | *Romneya coulteri* |
| | Meadow Rue | *Thalictrum polycarpum* |
| | Mesa Bush Mallow | *Malacothamnus fasciculatus* |
| | Monkeyflower | *Mimulus sp.* |
| | Mountain Mahogany | *Cercocarpus betuloides* |
| | Sage | *Salvia sp.* |
| | Showy Penstemon | *Penstemon spectabilis* |
| | Silktassel | *Garrerya elliptica* |
| | Stonecrop | *Sedum sp.* |
| | Sugarbush | *Rhus ovata* |
| | Toyon | *Heteromeles arbutifolia* |
| | Tree Mallow | *Lavater assurgentiflora* |
| | Valley Oak | *Quercus lobata* |
| | Western Redbud | *Cercis occidentalis* |
| | Wild Lilac | *Ceanothus sp.* |
| | Woolly Blue Curls | *Trichostema lanatum* |
| | Yarrow | *Achillea millefolium* |

**Attract Butterflies** – These plants provide a food source for butterflies and caterpillars.

| | | |
|---|---|---|
| | Buckwheat | *Eriogonum sp.* |
| | Butterfly Bush | *Asclepias fascicularis* |
| | Coyote Mint | *Monardella ssp.* |
| | Encelia | *Encelia sp.* |
| | Golden Yarrow | *Eriophyllum lanatum* |
| | Guadelupe Island Rock Daisy | *Perityle incana* |
| | Lupine | *Lupinus sp.* |
| | Mexican Marigold | *Tagetes lemonii* |
| | San Clemente Island Cherry | *Munzithamnus blarii* |
| | Seaside Daisy | *Erigeron glaucus* |
| | Yarrow | *Achillea sp.* |

Common Yarrow[2]

Western Redbud[14]

# Plant Water Needs
## High, Moderate or Low

| Common Name | Plant Type | |
|---|---|---|
| Alum Root Hybrids | Perennial | M |
| Alum Root/Coral Bells | Perennial | M |
| Apache Plume | Shrub | L |
| Bearberry | Ground Cover (GC) | M |
| Bigberry Manzanita | Shrub / GC | L |
| Bigleaf Lupine | Perennial | L |
| Black Sage (creeping) | GC | L |
| Blue-eyed Grass | Perennial | L |
| Bush Anemone | Shrub | M |
| Bush Sunflower | Shrub | L |
| Butterfly Bush | Shrub | M |
| California Bay Laurel | Tree | M |
| California Buckwheat | Shrub / GC | L |
| California Evening-Primose | Perennial | L |
| California Flannelbush | Shrub | M |
| California Fuchsia | GC / Perennial | L |
| California Honeysuckle | Shrub | M |
| California Poppy | Perennial | L |
| California Redbud | Tree / Shrub | L |
| California Sycamore | Tree | M |
| California Wild Grape | Tree | L |
| Canyon Live-Forever | Perennial | M |
| Chalk Dudleya | Perennial | M |
| Chaparral Currant | Shrub | L |
| Cleveland Sage | Shrub | L |
| Cleveland's Beardtongue | Perennial | L |
| Coast Live Oak | Tree | L |
| Coast Silktassel | Shrub | M |
| Common Monkeyflower | Annual / Perennial | H |
| Common Sage | Perennial | M |
| Common Yarrow | GC / Perennial | L |

Red Hot Poker[30]

Coyote Mint[27]

| Common Name | Plant Type | |
|---|---|---|
| Cotoneaster | Shrub / GC | M |
| Coyote Bush | Shrub / GC | L |
| Creeping Mahonia | GC | M |
| Creeping Wire Vine | GC | M |
| Deergrass (Dwarf Mullee) | Perennial | M |
| Desert Beauty/Indigo Bush | GC | L |
| Desert Marigold | Perennial | L |
| Desert Willow | Tree | L |
| Desert/Apricot Mallow | Perennial | L |
| Douglas Iris | Bulb | L |
| Dymondia Silver Carpet | GC | L |
| English Lavender | Perennial | L |
| English Thyme | GC | L |
| Evergreen Currant | Shrub / GC | M |
| Fairy Duster | Shrub | L |
| Firecracker Penstemon | Perennial | L |
| Fremont's Cottonwood | Tree | M |
| French Lavender | Perennial | L |
| Giant Wild Rye | Grass | L |
| Globe Gilia | Annual | M |
| Golden Currant | Shrub | M |
| Golden Yarrow | Perennial | M |
| Greek Oregano | Perennial | M |
| Harvest Brodiaea | Perennial | L |
| Heart-leaf Penstemon | Shrub | L |
| Hollyleaf Cherry | Tree/Shrub | L |
| Hummingbird Sage | Perennial | L |
| Interior Live Oak | Tree | L |
| Island Bush Poppy | Shrub | L |
| Island Bush Snapdragon | Shrub | L |
| Lemonade Berry | Shrub | L |

| Common Name | Plant Type | |
|---|---|---|
| Leopard Lily | Perennial | H |
| Matilija Poppy | Shrub | L |
| Mexican Bush Sage | Shrub | L |
| Mexican Elderberry | Tree / Shrub | L |
| Mexican Whorled Milkweed | Perennial | M |
| Mock Orange | Shrub | M |
| Mosquito Fern | Perennial | H |
| Oneleaf Onion | Perennial | M |
| Oregon Grape | Shrub | M |
| Our Lord's Candle | Shrub | L |
| Pacific Sedum Stonecrop | GC | L |
| Pacific Wax Myrtle | Shrub/Tree | M |
| Palmer's Penstemon | Perennial | L |
| Panamint Beard Penstemon | Perennial | L |
| Parry's Nolina | Perennial | M |
| Pink-flowering Currant | Shrub | M |
| Purple Needle Grass | Perennial | L |
| Purple Sage | Shrub | L |
| Red Creeping Thyme | GC | L |
| Red-flowering Currant | Shrub | M |
| Red-Hot Poker | Perennial | L |
| Rockrose | Shrub | L |
| Rosemary | Shrub | L |
| Santa Barbara Ceanothus | Shrub / GC | L |
| Scarlet Bugler | Perennial | L |
| Scarlet/Western Columbine | Perennial | M |
| Scrub Oak | Tree | L |
| Sea Lavender / Statice | Perennial | M |
| Seaside Daisy / Beach Aster | Perennial | H |

Purple Needle Grass[13]

Sulphur Buckwheat[1]

| Common Name | Plant Type | |
|---|---|---|
| Sheep Fescue (Blue) | Grass | L |
| Showy Penstemon | Perennial | L |
| Sky Lupine | Perennial | L |
| Society Garlic | Bulb | L |
| Spanish Lavener | Perennial | L |
| Spreading Rush | Perennial | H |
| Spring Cinquefoil | Perennial | M |
| St. Catherine's Lace | Shrub / GC | L |
| Sticky Monkeyflower | Perennial | L |
| Sulphur Buckwheat | Shrub / GC | L |
| Sweet Lavender | Perennial | L |
| Tidy Tips | Annual | L |
| Toyon | Shrub | L |
| Tree Poppy | Shrub | L |
| Twinberry Honeysuckle | Shrub | M |
| Valley Oak | Tree | M |
| Western Azalea | Shrub | H |
| Western Blue Flax | Perennial | H |
| Western Pennyroyal | Perennial | L |
| Western Spice Bush | Shrub | M |
| White Mariposa Lily | Perennial | M |

# Firewise Landscape and Fuel Modification Zones

Courtesy of the County of Los Angeles Fire Department and Forestry Division

A fuel modification plan identifies specific zones within a property that are subject to fuel modification. A fuel modification zone is a strip of land where combustible native or ornamental vegetation has been modified and/or partially or totally replaced with drought tolerant, fire resistant plants.

Fuel modification reduces the radiant and convective heat, and provides fire suppression forces a defensible space in which to take action. Fuel modification zones are strategically placed as a buffer to open space, or areas of natural vegetation and generally would occur surrounding the perimeter of a subdivision, commercial development, or isolated development of a single-family dwelling.

## Zone Definitions:

### ZONE A – Setback Zone

- Moderate to high water use plants can be used in this area which encompasses the first 20' around the structure.
- No trees should be planted within the first 10' of this zone.
- Trees in this zone should not be planted where branches encroach within 10' of a chimney or roof.
- Vegetation should be low growing, 2' tall or less, except for specimen plantings.
- This zone should be free of any wooden structures such as decks and patios.

### ZONE B – Irrigated Zone

- Extends outward from Zone A for 80' or more.
- The first 20-30' of this zone can include plants in Zone A, but low to moderate water use plants are more desirable.
- Shrubs should be spaced at least three times the height of the plant away from each other (edge to edge) or groups of shrubs to a maximum of 15'.
- Any turf used in Zone B should be placed to act as a buffer between a structure and a potential fire hazard.
- Irrigation should be used primarily to maintain plant health and moisture during periods of fire danger.

### ZONE C – Thinning Zone

- Extends outward from Zone B for up to 100'.
- This zone will not normally be irrigated except to establish supplemental plantings.
- This zone contains mostly thinned native vegetation, but may include vegetation planted for erosion control and slope stability.

### ZONE D – Interface Thinning Zone

- This zone extends outward from Zone C for up to 100'.
- Modification in this zone is usually limited to thinning of existing vegetation to reduce fuel load.

### ALL ZONES

- Tree spacing should be 30' between canopies.
- Zone A + B + C + D will be less than or equal to a distance of 200' measured horizontally from the structure.

Salvia azurea var. grandiflora (Pitcher Sage)

Abelia 'Edward Goucher'

Salvia azurea var. grandiflora (Pitcher Sage) is a clump-forming, shrubby perennial with beautiful wands of sky blue flowers, up to 12 in. long (30 cm). Blooming from midsummer to frost, the elegant flowering wands are borne on slender stems clad with long, narrow, grayish-green leaves. Hardy, this Salvia enjoys an upright habit until midsummer, but will sprawl over nearby plants when it begins to bloom.

Read More Add to Collection

Award-winning Abelia 'Edward Goucher' is a compact, semi-evergreen shrub with upright, gracefully arching stems bearing glossy, oval, dark green leaves with a bronze tinge when young. In midsummer, abundant clusters of lilac-pink, funnel-shaped flowers adorn the bush until fall. Their attractive bronze-tinged calyces further enrich the display and persist well after the flowers fall.

## Cercis chinensis 'Avondale' (Chinese Redbud)

Award-winning Cercis chinensis 'Avondale' (Chinese Redbud) is an upright, deciduous shrub or small tree with profuse, densely-clustered, tiny, rose-to-magenta flowers that arise before the foliage in spring. The cheerful blossoms literally cover the tree in a spectacular floral display. They last for several weeks before being joined by large, heart-shaped, glossy green leaves, tinted red-purple when they unfurl.

## Cercis occidentalis (Western Redbud)

Providing four-season interest, Cercis occidentalis (Western Redbud) is a deciduous shrub or small tree of great beauty. In spring, its silvery-gray branches contrast beautifully with masses of brilliant magenta flowers which are attractive to hummingbirds, bees, butterflies, and other native pollinators. The cheerful blossoms give way to long, purple-brown seed pods which adorn the branches in summer.

## Cotinus 'Grace' (Smokebush)

Cotinus 'Grace' (Smokebush) is a vigorous deciduous shrub noted for its attractive foliage of rounded leaves. Emerging bright wine red in spring, the leaves mature to dark red in summer, before turning glowing shades of red, orange, and gold in fall. Huge, feathery, purplish-pink flower plumes cover the plant with fluffy, hazy 'smoky' puffs in summer. When viewed en masse, these have a wispy 'smoke-like' appearance, hence the common name of Smoketree or Smokebush. A plant of exceptional beauty offering multiple seasons of interest.

# Key to plant symbols

## Soil preference

- Well-drained soil
- Moist soil
- Wet soil

## Preference for sun or shade

- Full sun
- Partial or dappled shade
- Full shade

## Hardiness ratings

- ❄❄❄ Hardy plants
- ❄❄ Plants that survive outside in mild regions or sheltered sites
- ❄ Plants that need protection from frost over winter
- Tender plants that do not tolerate any degree of frost

# Disguising boundaries

A visible boundary, such as a fence or wall, can make a yard feel small and claustrophobic. Concealing boundaries with plants will radically improve the appearance of a yard, transforming it into an attractive space.

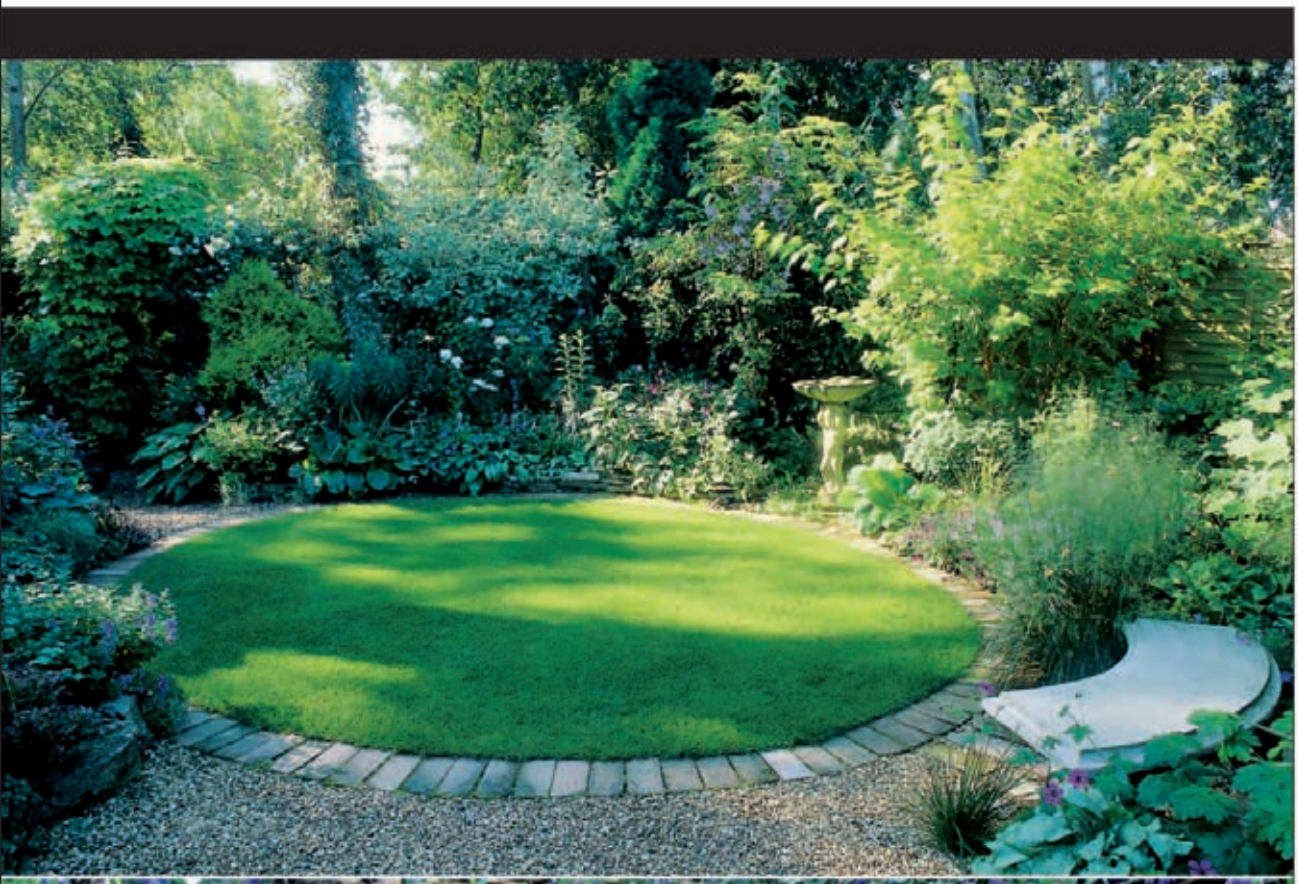
*Pictures clockwise from top left*

**Back fence disguise** In many small yards, the most obvious boundary is the back fence, which, if visible, immediately gives away the length of the yard. By creating a mixed border directly in front, using a range of plants that will grow as tall as, or taller than, the fence, you will succeed in blurring the edges of your lot. Make sure the border is a reasonable depth: a narrow strip in front of the fence, deep enough for only one plant, is likely to draw attention to the boundary rather than disguise it.

**False perspective** One of the most effective ways to disguise a boundary and also make a yard seem larger is to create a false perspective. For example, in a yard that appears short, make the borders running down the sides of the yard taper outward so that they are wider at the far end, making the yard appear longer. Another visual trick is to draw the eye away from the boundaries with a central, circular lawn or paved area, and surround it with dense plantings. Evergreen shrubs will ensure that the effect lasts all year.

**Plant screen** Dividing up the yard with various plant screens so that the entire yard is never completely visible from any one position will help make it feel larger and shift the emphasis away from the boundaries. Even a small lot can be divided up in this way using trellis or woven willow screens as supports for climbing plants; these also help to maximize growing space.

**Courtyard enclosure** Having a small garden does not mean that you should restrict yourself to small plants; in fact, doing so serves to underline a yard's limited size. Positioning a selection of quite large plants in front of fences or walls in generous-sized beds that have been pushed to the edges of the lot will help to maximize space in the center of the yard, creating a courtyard. The plants will also help to hide fences and walls.



## Using color

The color provided by flowers and foliage is particularly valuable in a garden. It can be used in a number of different ways, perhaps to evoke a particular mood or to give areas of the garden a theme or look.

*Pictures clockwise from left*

**Rich colors** If you spend a fair amount of time enjoying your garden from indoors, it makes sense to provide displays of rich color that are easily visible from the house, perhaps in pots and containers on the patio, or in beds and borders close to the windows. Harmonious colors that blend well together create a strong but restful feel; use softer, pastel hues farther away from the house because they show up better at a distance than saturated colors.

**Monochrome planting** A garden or border composed of mostly white-flowering plants creates a cool, calming feel that is most striking at dusk, when the blooms glow in the fading light. Try using cream and pale yellow flowers, as well as very pale pink and blue ones, to prevent the effect from becoming stark and clinical. Silver-leaved and variegated plants will provide interest once the flowers have faded.

**Hot hues** Fiery colors, such as reds, oranges, and intense pinks, demand attention, but they should be used with care: they attract the eye away from softer shades and, if planted at the far end of the garden, may make the yard feel smaller. Often the simplest way to deal with hot-hued plants is to group them together and create a condensed and spectacular injection of color. Alternatively, combine them with contrasting shades, such as rich blue or purple, to mitigate the effect.

**Serene green** It is important to remember that green is also a color, and is the most commonplace in virtually every garden. There are many different shades of green but, generally, it has a restful effect, and gardens that are planted for foliage tend to be serene spaces. Set against other colors, though, green generally fades into the background, so use plants with variegated foliage or white or pastel-colored flowers to shine out and provide additional interest.

# Focal points

Gardens often benefit visually from a dramatic or arresting focal point, be it a statue, pot, or plant, which provides a point of reference within the design where the eye can rest.

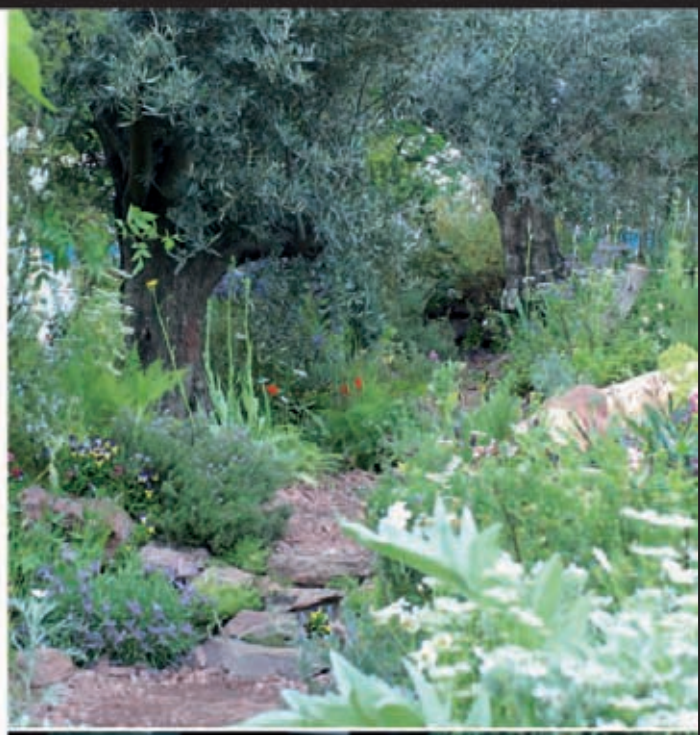
*Pictures clockwise from top left*

**Eye-catching trees** In a garden that seeks to recreate the wild, focal points need to be natural objects, such as rocks or specimen plants. In this Mediterranean-style garden, the gnarled trunks and silvery foliage of a pair of old olive trees are as arresting as any classical sculpture.

**Winding steps** Even a utilitarian feature such as a flight of steps can provide a focal point, as long as it is well executed. Winding steps passing through lush foliage lead the eye on to brighter, more vibrant flowers and foliage, which then act as a visual stopping point.

**Dramatic containers** Attractive pots and containers, planted or otherwise, are one of the simplest ways of creating a focal point. Used alone or in groups, they can be placed in a border, on a patio, or at the end of a pathway, perhaps terminating a vista. Large, impressive pots are often best left empty; others can be enhanced with a dramatic plant, such as a *Dasylirion*.

**Focus on color** Brightly colored plants make small-scale focal points in beds and borders. The vivid flowers of bulbs, such as these orange tulips, provide short-term accents, lifting other plantings and heightening interest.



# Themed planting schemes

Some of the most successful gardens are developed around a particular theme or idea that helps to bind the planting and design together. Selecting plants that fit the overall concept helps evoke the correct spirit and feel, which, in turn, lends a touch of authenticity to the garden.

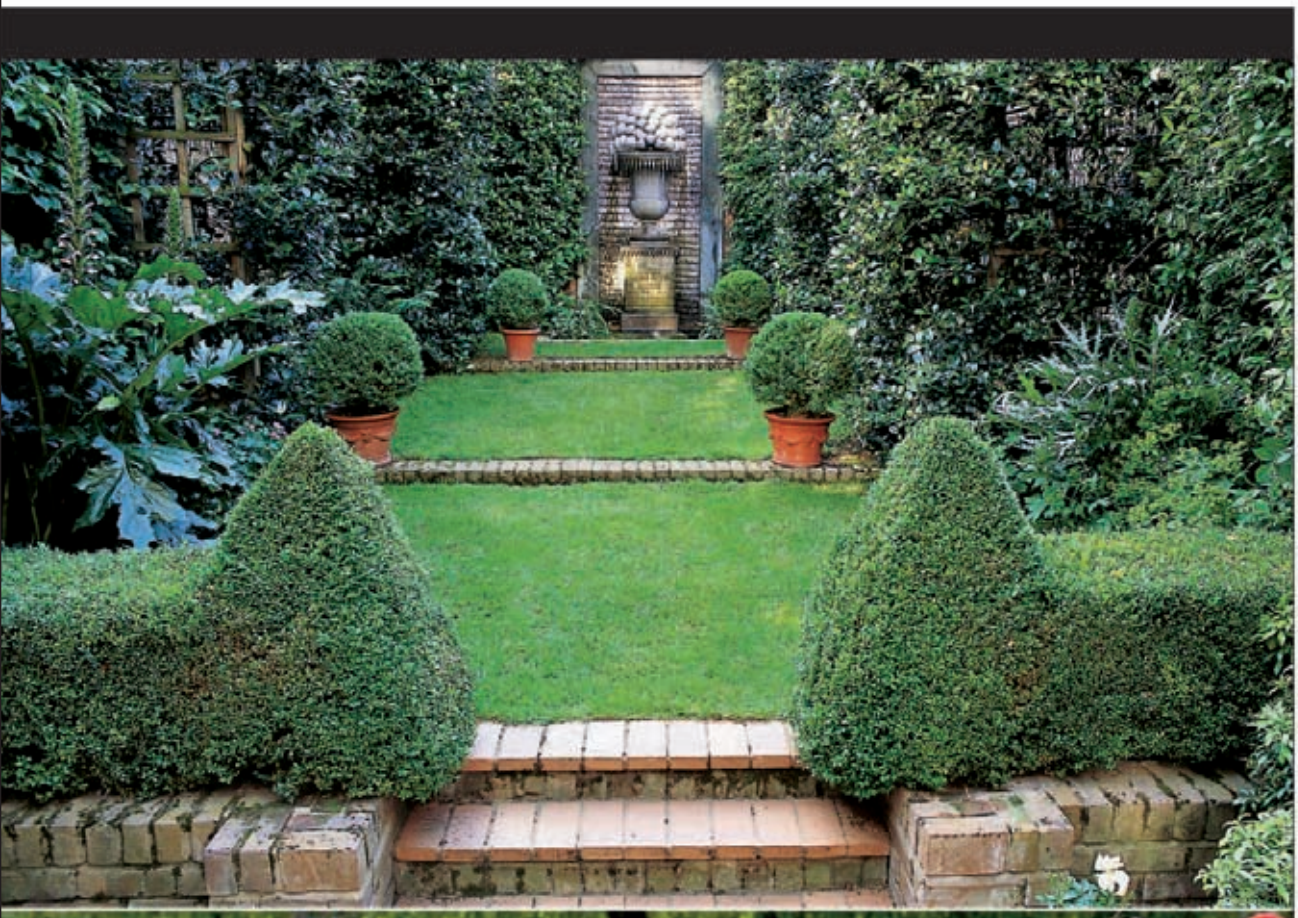
*Pictures clockwise from top left*

**Lush and subtropical** There are many hardy and borderline hardy plants that can be used to create a subtropical-style garden. Generally, the lush feel is provided by foliage plants. Large specimens of hardy *Trachycarpus* palms, bamboos, phormiums, and tree ferns will provide structure; in summer, containers can be filled with tender plants such as begonias, cannas, *Lantana*, and gingers (*Hedychium*), which produce exotic flowers.

**Classic Italian** Italianate gardens tend to be rather formal, with plenty of topiary and clipped evergreens, such as boxwood (*Buxus*). The layout is usually simple and the planting restrained, limited to a few favorites, such as acanthus, agapanthus, olives, slender conifers, jasmine, and herbs. Classical statuary plays an important role, often terminating a vista, and specimen plants in containers may feature, perhaps used along a terrace to introduce a sense of repetition and rhythm to the garden.

**Meadow planting** Informal and naturalistic, meadow planting uses a limited palette of different plants mixed randomly together in large groups. These schemes work well in large, open expanses and tend to be short-lived—many of the plants used are annuals, such as poppies (*Papaver*) and cornflowers (*Centaurea cyanus*). However, perennials can also feature, and the planting style can be scaled down to more modest-sized borders.

**Moroccan oasis** Water is a vital element for a Moroccan theme, and a wall fountain, perhaps with a blue-tiled surround, would make an ideal feature. Most of the plantings should be in pots—pelargoniums, date palms, agaves, and other succulents are suitable choices—but avoid having too many plants. A few large foliage plants in darker corners, and climbers, such as *Trachelospermum*, scrambling up the walls would also fit in very well.



## Themed planting schemes *continued*

*Pictures clockwise from top left*

**Mediterranean style** Gravel, terra-cotta pots, and a sunny site all help to create a Mediterranean feel. Avoid filling the garden with too many plants—the general scheme should not be too lush—and try a few formal elements, such as clipped boxwood balls. Olive trees in pots can spend summer outside, while more permanent plants could include lavender (*Lavandula*), Cistus, and one or two exotics, such as Yucca.

**Asian calm** Japanese-style gardens often feature a few manicured plants, such as Japanese maples (*Acer japonicum*), dwarf pines, bamboos, *Ophiopogon*, and *Ilex crenata,* set in a rock and gravel landscape. Strategically positioned bonsai specimens add a dramatic touch to the overall theme.

**Cottage effects** Borders overflowing with flowers are typical of cottage gardens. Old favorites include delphiniums, foxgloves (*Digitalis*), Shasta daisies (*Leucanthemum* x *superbum*), and lavender (*Lavandula*), with sweetly scented roses and self-seeding annuals completing the informal look.

**Modern mixes** Architectural plants, such as tree ferns, phormiums, and *Tetrapanax*, are the mainstays of highly designed contemporary gardens. Grasses and small-scale, naturalistic planting schemes are also popular, their soft foliage forms contrasting well with hard modern landscaping materials, such as concrete, glass, and steel.

# Seasonal interest

Watching the way a garden changes its character with the seasons is part of the joy of gardening. To get the most from your garden, it should be designed and planted to provide interest for every day of the year. Each season has its own distinctive feel and appearance, and a well-designed garden will include plants that reflect this.

**Spring** (*top right*) As the days lengthen, the garden quickly wakes from its winter rest. Bulbs, such as daffodils and crocuses, produce showy flowers, while other herbaceous plants begin to emerge from the ground, and deciduous shrubs and trees produce fresh, verdant growth.

**Summer** (*right*) For many gardeners, this season represents the high point of the year. Most herbaceous plants reach their zenith, filling out borders and blooming for several months, while annuals flower and set seed. Leafy trees and shrubs provide structure, and tender plants flourish in the mild summer months.

**Fall** (*bottom right*) This is arguably the most colorful and plentiful season. Late-flowering plants, such as asters and dahlias, blaze in borders, while many trees and shrubs produce vivid berries and fruits. The leaves of many deciduous plants also brighten up the garden with rich hues before falling. In the moist and still warm conditions, some bulbs, such as *Colchicum*, provide a welcome freshness.

**Winter** (*opposite page*) Once all the leaves have fallen, the shape and structure of the garden and its plants can be properly appreciated. This is a season of quiet, subtle beauty. Trees and shrubs, such as silver birch (*Betula pendula*) and *Cornus* with its red-colored stems, and evergreen plants, as well as the faded seedheads of herbaceous plants, provide interest. A few plants also produce delicate, often sweetly scented flowers. As cold weather sets in, frost and snow dust the plants, creating a magical feel.

# Spring beds and borders

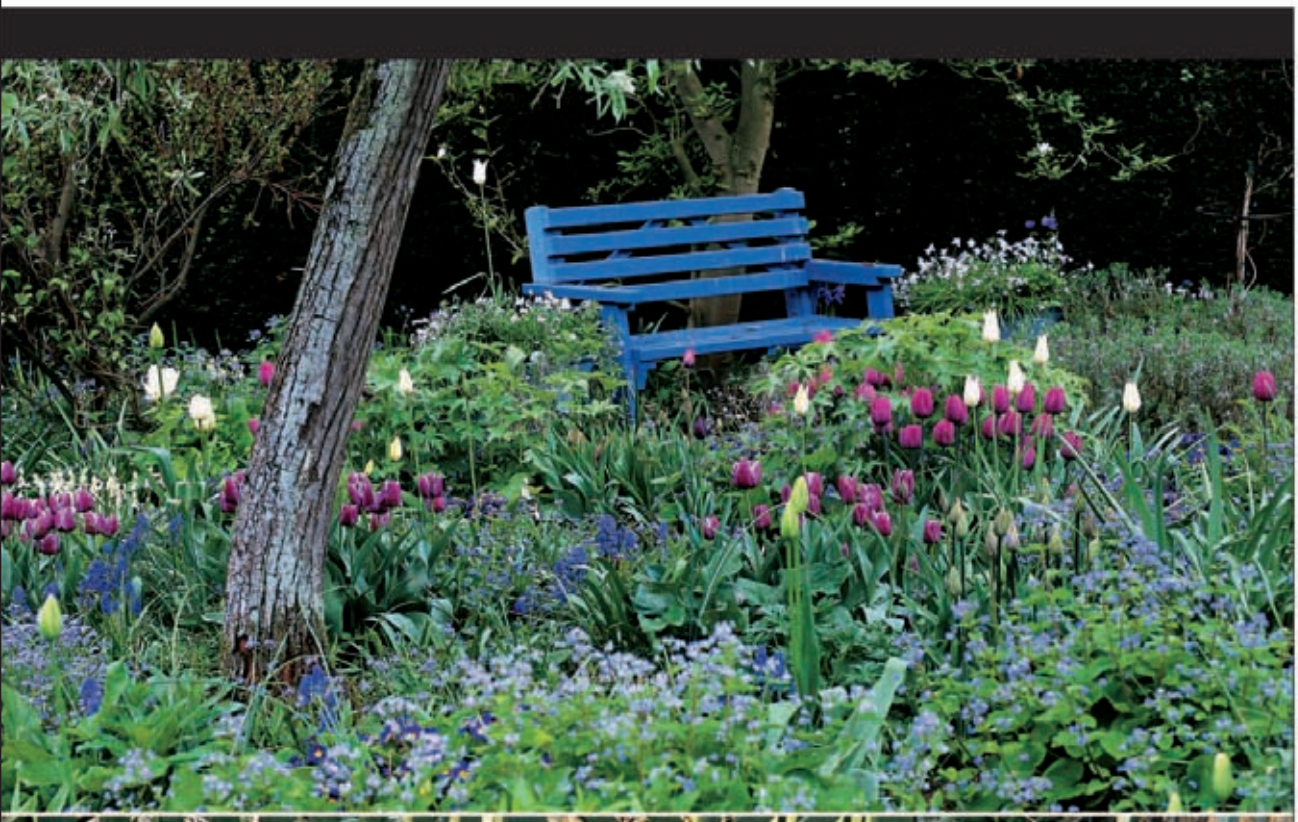
No season is more eagerly anticipated than spring. After the dark, cold days of winter, the garden bursts into life with verdant growth and colorful flowers, marking the start of a new gardening year. In late spring, many gardens look their freshest, resplendent with the soft, glowing greens of young foliage.

*Pictures clockwise from left*

**Colorful climbers** Walls and fences can be clothed with a range of different climbers that will flower in spring. Wisteria, grown for its waterfalls of scented purple or white flowers, is perhaps the best known. It is, however, a large plant and needs restrictive pruning to keep it manageable. Alternatives include *Clematis montana* in white or pink, and *Akebia quinata* with purple blooms, although these climbers are also potentially large. More suited to a small garden are *Clematis alpina, C. macropetala*, and the early honeysuckle *Lonicera periclymenum* 'Belgica' with its deliciously scented flowers.

**Vibrant bulbs and early perennials** In beds and borders, herbaceous plants push through the soil, growing quickly in the damp, mild conditions. Many will flower early, especially those that enjoy woodland conditions, such *as Pulmonaria, Primula, Dicentra, Doronicum, Epimedium,* and *Anemone.* Some of these perennials can be grown successfully with spring bulbs, such as tulips and daffodils, injecting extra interest into plantings and helping to mask yellowing bulb foliage as the season progresses.

**Carpets of spring flowers** In less formal areas of the garden, where a more naturalistic display is desired, it is possible to plant and even naturalize some bulbs in grass. Snowdrops (*Galanthus*) and crocuses that flower in early spring can be interplanted with fritillaries, tulips, daffodils (*Narcissus*), and *Camassia* to create a display that will last until early summer. Areas under mature trees are ideal for this kind of treatment, but avoid mowing the grass until the bulb foliage has died away.



# Summer beds and borders

Summer is the season of unrestrained color, when most beds and borders are at their best. If well planted, the garden should provide a succession of flowers that lasts for months on end.

*Pictures clockwise from top left*

**Mixing colors** Planting a mix of herbaceous perennials and annuals is a quick and easy way to provide striking contrasts. Color-themed plantings that use a restricted color palette are effective at creating different moods. Contrasting colors evoke drama, while those that blend together produce a more relaxed feel.

**Continuous color** Many perennials run out of steam as the summer progresses, especially in times of drought or extreme heat. Others, though, can be relied on to flower well into fall, especially those that are natives of warmer climates, such as *Crocosmia* and *Rudbeckia*.

**Calming foliage** Without some order, too many bright flowers can become rather overpowering, especially in a small space. The mitigating effect of foliage can help create a calmer effect, softening bright colors. Silvery leaves, such as those of *Artemisia*, used with whites, creams, and pale pinks produce a cool feel; deep green foliage contrasts well with brightly colored flowers.

**Summer bulbs** Summer-flowering bulbs, such as lilies, gladioli, and *Galtonia*, are often overlooked but, planted directly into borders or put in pots and plunged into the ground, they pack a powerful punch of color.

## Fall beds and borders

As the days shorten, color and interest in the garden come from new sources: the leaves of some plants acquire fiery tints, and fruits and seedheads replace many flowers. Some blooms are at their best during fall, too.

*Pictures clockwise from left*

**Deciduous trees** Trees and shrubs, such as Japanese maples (*Acer japonicum*) and *Rhus*, produce autumnal tints that provide a spectacular backdrop to other plantings. The colored leaves remain eye-catching once they have fallen, especially around the flowers of late-blooming perennials and bulbs, such as *Cyclamen*.

**Structural seedheads** Some summer-flowering perennials, such as *Echinops*, *Allium*, *Agapanthus,* and many grasses, produce attractive seedheads that last well into winter. They look particularly striking in the slanting fall light, decorated with cobwebs or, later, frost.

**Colorful fruits** Many shrubs and trees produce handsome, long-lasting fruits at this time of year; certain roses, in particular, carry ruby hips, as long as they are not pruned in fall. Consider leaving other plants unpruned, such as *Viburnum* and *Sorbus*, to help provide birds with food.

**Perennial color** Some perennials, such as *Aster, Chrysanthemum, Cyclamen*, and *Saxifraga fortunei*, will produce vibrant flowers until the first hard frost, and look wonderful in fall borders. They can also be useful in containers to inject color into areas of the garden that are of little interest at this time of the year.

# Winter beds and borders

Gardens are often neglected in winter once most showy flowers have faded, but with the right plants, they can still be enchanting places at this time of year. Plants with winter interest often have special, rather subtle qualities, such as sweetly scented flowers, attractive stems, foliage, seedheads, berries, or structural shapes.

*Pictures clockwise from top left*

**Winter flowers** Hellebores, such as *Helleborus* x *hybridus*, are among the best winter-blooming plants. Flowering from midwinter to mid-spring, these clump-forming evergreen perennials are easily grown in light shade in any good soil, and form good ground cover when planted in drifts. Other perennials with winter interest worth seeking out include mauve-flowered *Iris unguicularis* and *Arum italicum* 'Marmoratum', with its white-veined leaves.

**Transient beauty** Frost and snow add an element of short-lived beauty to the garden in winter, often transforming it overnight. A light covering of snow or a hard frost can enhance structures, highlighting architectural features and plants and briefly changing the whole feel of a garden.

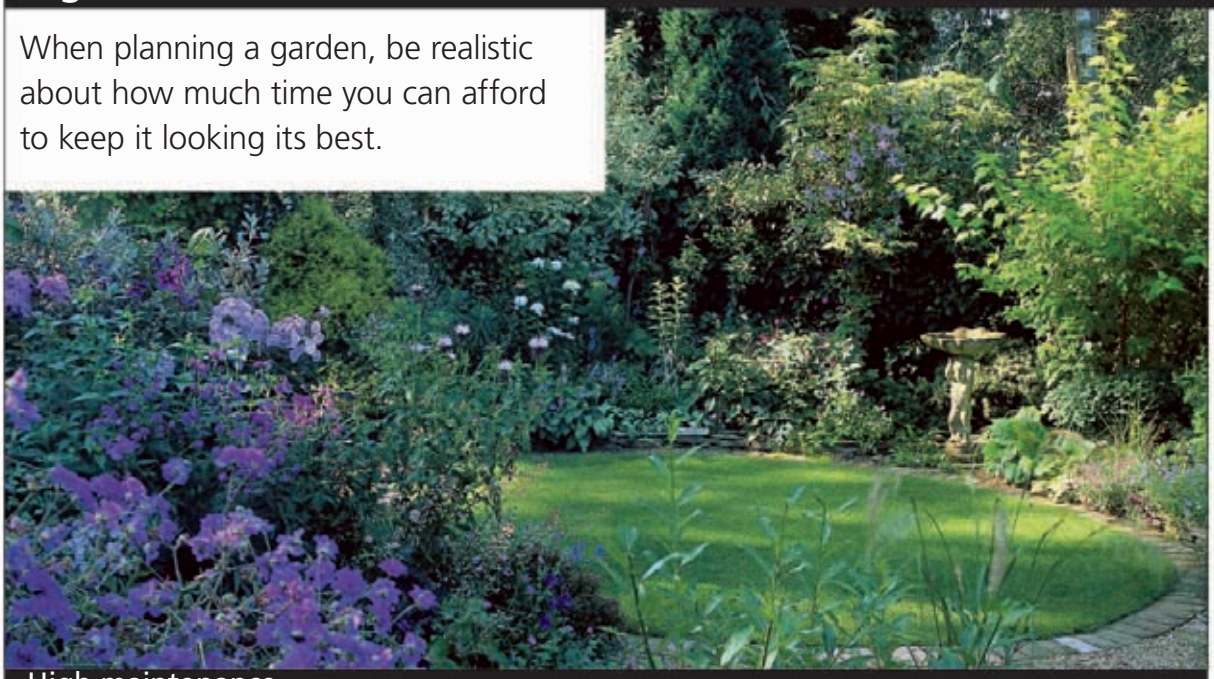
**Scented highlights** Mahonias are among the finest evergreen shrubs for winter, with their spiny foliage and sweetly scented yellow blooms, followed by blue-tinged berries. They are also useful for their architectural form, which makes them an attractive backdrop for other plants such as *Euonymus*, with its colorful fruit.

**Graceful grasses** The seedheads of some grasses will survive well into winter, providing a touch of unexpected grace to plantings, especially when dusted with frost. Translucent, they allow views through to plants behind, such as the fruit-laden branches of a crabapple (*Malus*).

**Scented shrubs** Some shrubs flower in winter, such as witch hazel (*Hamamelis*) with its orange, yellow, or red spiderlike blooms. Other shrubs worth considering for their delicious scent include the honeysuckle *Lonicera* x *purpusii* and *Chimonanthus praecox*.

# High and low maintenance

When planning a garden, be realistic about how much time you can afford to keep it looking its best.



## High maintenance

**Gardens for plant lovers** These gardens tend to be stocked with a wide range of choice plants, which need their specific growing requirements matched in order to grow well. Careful placing of plants and constant manipulation of growing conditions by gardeners will keep these gardens looking their best, and regular attention will be required to keep plants from outgrowing their space.

**Dense planting** Filling a garden with plants may reduce weeding, but competition for light and water causes problems. High-maintenance plants include dahlias, which may need planting and lifting each year, annuals grown from seed, plants with specific watering, feeding, or pruning needs, and those prone to pests and diseases. A lawn also needs weekly mowing to keep it looking good.

**High-maintenance planting suggestions**

- *Aster* (some)
- *Astrantia*
- *Buxus* (if kept clipped)
- *Canna*
- *Clematis* (some)
- *Cornus sanguinea* 'Winter Beauty'
- *Dahlia*
- *Dicksonia antarctica*
- *Echinacea purpurea*
- *Erysimum*
- *Helenium*
- *Hosta*
- *Lavandula* (lavender)
- lilies
- *Melianthus major*
- roses (some)
- *Sambucus racemosa* 'Plumosa Aurea'
- tulips

Tulip bulbs should be planted in late fall.

*Hosta* 'June', like all hostas, is loved by slugs.

Prune *Cornus sanguinea* in early spring.

*Lilium regale* bulbs should be planted in spring.

## Low maintenance

**Easy-care gardens** These are a good choice for people who have little spare time but still want an attractive outdoor space. Lawns can be replaced with patios or decks, and the soil covered with a special membrane to cut down on weeding, and topped with bark or cobbles after planting. Irrigation systems can be installed, and plants chosen that do not need much attention.

**Undemanding planting** This can provide year-round interest and yet needs little attention. Large specimen plants provide immediate impact. Evergreen shrubs and trees are good because most need little pruning and do not drop leaves in fall. Minimal use of herbaceous plants lessens end-of-season work, and using well-spaced larger plants reduces watering and trimming.

**Low-maintenance planting suggestions**

- *Acer*
- *Arbutus unedo*
- *Aucuba japonica*
- *Choisya ternata* Sundance
- *Cotoneaster horizontalis*
- *Fatsia japonica*
- *Hemerocallis* (day lily)
- *Ilex aquifolium* 'Silver Queen'
- *Jasminum nudiflorum*
- *Mahonia*
- *Nandina domestica*
- *Phormium*
- *Photinia* x *fraseri* 'Red Robin'
- *Phyllostachys nigra*
- *Stipa tenuissima*
- *Trachelospermum asiaticum*
- *Vinca* (periwinkle)

*Ilex aquifolium* 'Silver Queen' has beautiful evergreen foliage.

*Stipa tenuissima* is a trouble-free, airy grass.

*Hemerocallis* 'Corky' is ablaze with golden blooms in summer.

*Cotoneaster horizontalis* has bright red fall berries.

# Choosing a planting style

When planting your garden, if you decide to follow a particular style, first ensure that it is practical and fits your lifestyle.

## What do you want?

Find inspiration for your yard by visiting other gardens, and looking at books, magazines, and television shows. If you long for a tropical garden with exotic plants, such as palms and other architectural specimens, you can achieve it with the use of containers on a sun-drenched terrace, even in cold regions.

## What do you need?

If entertaining outdoors is important to you, a large patio with a dining/barbecue area will be useful, while a lawn is a good idea if children are likely to play in the yard in summer. Your lifestyle may dictate that you have a low-maintenance garden with plants that are easy to care for but look good all year. Consider also how much privacy you need.

Examine the visual appeal of your chosen scheme. Will you include plants with impact to create impressive planting schemes? Or would you prefer a themed garden with an exotic feel, or simply an oasis of tranquillity? When selecting plants, make sure you choose those that will suit the style of garden you have in mind.

## Keeping it neat

A wonderful garden filled with unusual plants and flowers is all very well, but it may require a great deal of time to keep it in tip-top condition. When planting and designing a garden, decide how much time you can spare to care for it. Some planting styles require less effort than others to keep them looking good. A formal garden with a central lawn, for example, looks tidy once mown, but it may be better to reduce the area of grass or replace it with gravel or decking, if free time is limited. Planting in formal schemes tends to be confined to geometric-shaped beds or borders. Designs can be either high-maintenance, with a mix of perennials, annuals, and shrubs, or low-maintenance, with easy-care shrub borders.

## A natural approach

For many people, choosing a naturalistic planting style, using drifts of perennials or a large number of native plants, creates a garden that feels at one with nature. With this approach, you may also decide to avoid using chemicals on your plants, and adopt organic growing methods. Encourage birds, insects, and other wildlife into your garden to enrich your gardening experience, and create curved or sinuous borders for your informal planting designs.

# Planting style ideas

Setting a particular style for your planting and layout helps to create a feeling of cohesion, and makes selecting plants and garden objects much easier. The main hurdle is making a choice and sticking to it.

## Asian

An authentic Japanese garden is difficult to create, and requires discipline and subject knowledge. It is possible to use elements from the style, however, to create a distinctive Asian feel. Minimalist lines, the use of certain plants, rocks, raked gravel or slate chips, and focal points, such as stone lanterns, prove effective. Colors are restrained, derived mostly from foliage; showy flowers are seldom used.

**Planting suggestions**

- *Acer japonicum* (Japanese maple)
- *Camellia sasanqua*
- *Ophiopogon* 'Nigrescens'
- *Phyllostachys nigra*
- *Pinus mugo* 'Ophir'

**Maintenance tips** Keep raked gravel weed- and leaf-free: the garden should appear immaculate.

Maple foliage provides vibrant color in an Asian-themed garden.

## Knot gardens and parterres

Knot gardens are generally small-scale and feature low, clipped hedges, usually boxwood (*Buxus*) but sometimes *Santolina* or lavender (*Lavandula*), set out in simple patterns. Between the hedges are blocks of color, normally from bedding plants or colored gravel. Parterres are more ambitious in scale and design, but they also use low hedges with colorful flowers and often topiary. Both styles of garden are highly formal, labor-intensive, and best seen from above.

**Planting suggestions**

- bedding plants, e.g., dahlias, cosmos
- *Buxus sempervirens* (boxwood)
- culinary herbs
- *Santolina chamaecyparissus*
- *Taxus baccata* (yew)

**Maintenance tips** Clip the hedges 2–3 times a year to keep them neat.

A well-tended knot garden makes a fine garden feature, even without flowers.

## Modernist

The overall feel of most modernist gardens is one of simplicity and restraint, with planting often taking second place to hard landscaping, giving a minimalist feel. Plants are carefully selected and sited, with architectural specimen plants providing instant impact. The palette of plants is usually limited, with a restricted color theme, and maximum use is made of form and texture. Broad sweeps of perennials and grasses, often planted in a naturalistic way, provide summer color.

**Planting suggestions**

- *Acer japonicum* (Japanese maple)
- *Dicksonia antarctica*
- *Fatsia japonica*
- *Phyllostachys nigra*
- *Stipa tenuissima*
- topiary shapes, boxwood (*Buxus*), yew (*Taxus*)
- *Verbena bonariensis*

**Maintenance tips** Modernist gardens tend to be naturally low-maintenance, but be sure plants are well watered, especially when they are establishing, and top off mulches of gravel or aggregates as required.

Clipped boxwood balls in a sea of lavender give this garden a modern twist.

## Tropical

For sheer floral drama, few gardening styles can match a tropical border. These displays of exotic-looking plants, usually a mix of hardy and tender plants grown for both foliage and flowers, provide great interest in both summer and fall. Planting is informal, with plants massed together in profusion; huge bold leaves and vibrantly colored flowers predominate, while the displays improve as the season progresses. This style is labor-intensive, and displays usually last only until the first frost.

**Planting suggestions**

- *Canna*
- dahlias
- *Hedychium gardnerianum*
- *Melianthus major*
- *Musa basjoo* (banana)
- *Phoenix canariensis*
- *Phormium tenax*
- *Ricinus communis*

**Maintenance tips** Plant out a tropical border after the last frost date. Feed and water well for rapid, lush growth. Ensure that you protect tender plants well from winter cold.

Spectacular flowers and foliage provide high-impact summer displays.

## Cottage

A traditional cottage garden represents many people's idea of the ultimate garden. Planting tends to be informal, but contained within a simple, formal layout, which is usually little more than a network of paths. Flowering herbaceous perennials predominate, and these gardens are usually at their best in early summer. Later on, roses and clematis provide plenty of color, and in winter, well-chosen shrubs lend the garden structure once the flowers have faded. Colors are often soft and muted, giving a relaxed feel.

**Planting suggestions**

- *Astrantia*
- delphiniums
- *Dianthus* (pinks)
- *Digitalis purpurea* (foxglove)
- geraniums
- *Philadelphus*
- *Ribes* (flowering currant)
- roses

**Maintenance tips** Regular additions of garden compost in spring will keep perennials growing well. Remember to divide clumps of herbaceous plants every 2–3 years for healthy growth.

Borders overflowing with flowers are typical of the cottage-garden style.

## Contemporary

The contemporary garden is usually thought of as an extension of the home, a so-called "outdoor room" that often includes dining and seating areas. This modern and practical garden style often features expanses of paving or wooden decking, ideal for massed displays of brightly colored yet color-themed container plants in the summer. Beds tend to be filled with easy-care, usually evergreen plants, to provide year-round interest, and are often planted through a weed-suppressing membrane, topped with mulch to minimize aftercare.

**Planting suggestions**

- *Acer japonicum* (Japanese maple)
- *Astelia nervosa*
- *Aucuba japonica* (spotted laurel)
- *Photinia* 'Red Robin'
- *Choisya ternata*
- *Clematis armandii*
- *Pittosporum tenuifolium* 'Tom Thumb'

**Maintenance tips** Ensure that plants are well watered while establishing. Keep mulches topped off, and plant containers when frost has passed.

Wooden decking is used to give this garden a contemporary feel.

# The effects of exposure

The direction in which your yard faces affects the amount of sunlight it receives, while altitude influences temperatures. Take both factors into account when choosing your plants.

**Which way does your yard face?** Simply observing how much sun your yard receives gives an idea of its orientation. To work it out accurately, use a compass. Stand with your back to your house wall—the reading from here shows the direction the yard faces. South-facing yards get the most sun, north-facing sites the least.

Morning: areas that are in sun now may be in shade by the afternoon.

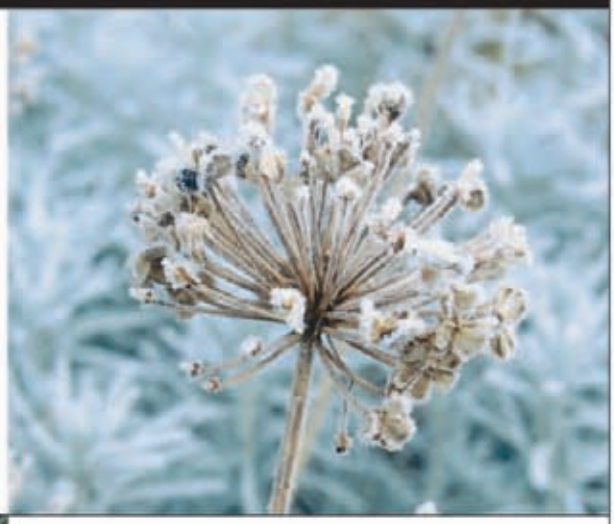
**Sunny and shady sites** Some yards are sunnier than others as a result of their exposure and other factors, such as shade-casting buildings, but in all sites, the amount of direct sun and the sun's position in the yard change as the day progresses. A south-facing yard will have sun all day, a north-facing one much less, or perhaps none in winter.

Sunny gardens are usually more desirable, but shade does have its advantages. These gardens are cooler, have a more humid microclimate, and are less prone to drought. There are many wonderful shade-loving plants that will not tolerate direct sun, while in a sunny garden, slightly tender plants from Mediterranean regions, for example, flourish. The key is to work with what you have.

Midday: the sun is overhead, so the garden receives maximum sunlight.

Evening: as the sun sets, the glancing light casts soft shadows.

**Beware frost pockets** Frost occurs when temperatures fall below freezing. Spring frosts can be particularly lethal in the garden, especially where many near-tender plants are grown. Even on a local scale, some sites will be more vulnerable than others, usually in areas where pockets of freezing air develop. Cold air is heavy, and sinks to the lowest point. If it cannot escape, it collects, forming a "frost pocket." Here, frosts will be harder and linger longer, and you may get a frost when other areas remain above freezing. Gardens in valleys or in a hollow often suffer badly. Hedges or walls may create or worsen the effect, preventing cold air from flowing away. Thinning a hedge, using trellis instead of a solid barrier, or leaving a gate open on cold nights may help.



**Creating microclimates** Even within a single garden, you may notice great differences in the growing conditions. A border by a sunny wall or fence will be far warmer and drier than one in the shade, perhaps beneath a tree, which is likely to be more humid with a more even temperature range. A low-lying area will remain wetter than a border at the top of a slope, and some parts of the garden may be sheltered, others exposed. Gardeners can capitalize on these differences; even in small areas, they allow you to grow a wider range of plants. A sunny spot can be enhanced with a raised bed to improve drainage for tender plants; low-lying areas could be turned into a bog garden for moisture-loving plants. You can make a windy area more sheltered with a permeable barrier, such as a trellis.

**Seasonal impact** The direction your yard faces gives it particular properties throughout the year. A north-facing garden, or border in front of a north-facing fence, will receive little sun in winter, remaining cold and damp, but temperatures will be more constant than in a south-facing area that is warmed after a sunny winter day, only to be chilled at night. Plants exposed to constant chill also start into growth later, but are affected less by late frosts. While potentially dank in winter, a north-facing area offers a cool retreat in summer, and lush, moisture-loving woodland plants will thrive there. Spring bulbs take advantage of the sun spots under bare deciduous trees, areas that receive little light in summer. Sunny patios are ideal for tender plants, but may get too hot and dry in summer for some plants.

# Understanding soil

Before you decide what to plant in your garden, take a look at the soil. The acidity or alkalinity of the soil and its composition determine what will grow, and an understanding of its properties helps you keep plants in good health.

## Types of soil

Soil comprises two elements: a mineral portion (tiny particles of weathered rock, larger gravel, and stones) and an organic portion (plant and animal remains, and living organisms). The most important part of the soil is found in the top 12 in (30 cm). Below this lies less fertile subsoil.

Soil particle size, the amount of organic matter, and available water determine soil characteristics. The smallest soil particles will form clay, those a little larger create silt, and even bigger particles form sandy soil. Soil with a mix of different particle sizes is known as loam.

The descriptions below will help determine your soil type:

**Chalk soil** Soil that is pale and contains chunks of white limestone (usually the underlying rock), and often flint, is chalk soil. It is free-draining and fertile, often rather thin, and almost always alkaline.

**Peat soil** Distinctively dark, peat soil is rich in organic matter that helps it retain soil moisture. Peat forms where wet, acidic conditions stop plant and animal remains from decomposing fully. Peat soil is usually acidic.

**Clay soil** Composed of more than 25 percent moisture-retaining clay particles, clay is heavy to dig and may be waterlogged in winter (it dries out in summer). Organic matter is easily trapped, resulting in good fertility.

**Silty soil** With particles not as fine as those of clay soil, silt is also fairly moisture-retentive and fertile. Silty soil tends to be dark in color, which is the result of the accumulated organic matter that it often contains.

**Sandy soil** Sandy soil is easy to spot, being light and free-draining. It is composed of relatively large individual soil particles that allow water to drain quickly.

## Testing the soil's acidity or alkalinity

Use a soil-testing kit to assess the acidity or alkalinity (pH) of your soil—the results will indicate what plants will grow well. Carry out several tests across the garden, using soil from just below the surface. Soil pH is measured on a scale of 1–14. Above neutral (7) is alkaline, below is acidic; pH 6.5 is usually considered the optimum.

Following the kit's instructions, add garden soil and water to the test tube provided and shake the contents well.

Compare results from around the garden with the chart provided: a red/yellow color shows an acidic soil; dark green an alkaline one.

## Testing sandy soil

To determine whether your garden has sandy soil, and thus may need regular irrigation and boosting with organic matter, carry out a simple test to examine the texture of the soil. Take your sample from just below the soil surface and repeat at intervals across the garden to ensure an even overall result.

Rub a small amount of soil between your fingers. If the soil has a gritty, granular feel, it is likely to contain a high proportion of sand.

Try to squeeze the soil into a ball—the grains of sandy soil will not stick together, but if it is loamy, the shape may hold a little.

## Testing clay soil

To check if you have clay soil, and thus soil that may become waterlogged in winter and be more difficult to dig than other soil types, remove small samples of soil from different spots around the garden from just below the soil surface. Clay soil will feel quite sticky and heavy when shaped in the hand.

Try to mold the soil in your hands—the particles of clay soil will hold together well and change shape when pressed.

Heavy clay can even be rolled into a thin cylinder; it will often appear smooth and shiny.

# Making the most of your soil

Different types of soil have differing characteristics, some aiding cultivation of certain plants, others providing a challenge to gardeners. Various techniques can be used to improve the soil to maximize its potential.

## Sandy soil

**Advantages** Sandy soil is free-draining, which prevents plants from becoming waterlogged in winter and aids the survival of species sensitive to wet conditions. It is easy and light to dig all year, and warms up quickly in the spring.

**Disadvantages** In dry conditions, plants will often require extra irrigation, and moisture-loving species will be unreliable in this soil. Sandy soil has a tendency to be poor, so you will need to apply plenty of plant food and organic matter.

**Improving sandy soil** Dig in large amounts of organic matter each year to help improve the soil's ability to hold water and nutrients. Mulches such as gravel help to keep in moisture. Digging in clay may also be useful.

### Plants for sandy soil

- *Acacia dealbata*
- *Calluna vulgaris* 'Silver Knight'
- *Catananche caerulea*
- *Cistus* x *hybridus*
- *Convolvulus cneorum*
- *Cotoneaster horizontalis*
- *Erysimum* 'Bowles' Mauve'
- *Euphorbia characias*
- *Euphorbia rigida*
- *Grevillea* 'Canberra Gem'
- *Helianthemum* 'Rhodanthe Carneum' ('Wisley Pink')
- *Helleborus argutifolius*
- *Iris unguicularis*
- *Melianthus major*
- *Olea europaea* (olive)
- *Pittosporum tobira*
- *Romneya coulteri*
- *Rosmarinus officinalis* (rosemary)
- *Solanum crispum* 'Glasnevin'
- *Verbena bonariensis*

*Abutilon* x *suntense*

*Allium hollandicum* 'Purple Sensation'

*Artemisia alba* 'Canescens'

*Bupleurum fruticosum*

*Lavandula stoechas*

*Perovskia* 'Blue Spire'

## Clay soil

**Advantages** Clay soil is usually highly fertile and many plants thrive in it. It also retains water well. The more clay soil is worked, the better it is for planting, as the soil gradually becomes more crumbly and drainage improves. Avoid working the soil when it is wet and easily compacted.

**Disadvantages** Despite its high fertility, clay soil has a number of problems that can be hard to tackle. In winter it may become waterlogged and impossible to dig. Attempts to work the soil in this state usually create compaction, where the soil particles are compressed, resulting in yet further waterlogging. In summer, the opposite problem occurs; clay bakes hard and even simple digging can be impossible. Even when the soil is manageable, it is heavy, breaking into large clods, and it is slow to warm up in spring.

**Improving clay soil** The key to success is often simply perseverance. By adding organic matter to the soil, you will eventually improve its structure, making it more crumbly and easier to work. In small areas, perhaps in a raised bed, dig in horticultural sand. Avoid walking on the garden when it is waterlogged and do not dig the soil when wet. Try to carry out most planting in spring or fall when the soil is more manageable. In areas where waterlogging is severe, you may need to install drains.

### Plants for clay soil

- *Alchemilla mollis*
- *Arum italicum* subsp. *italicum* 'Marmoratum'
- *Aruncus dioicus*
- *Aucuba japonica* (spotted laurel)
- *Berberis darwinii*
- *Buxus sempervirens* (box)
- *Campanula glomerata*
- *Carex elata*
- *Cornus sanguinea* 'Winter Beauty'
- *Digitalis purpurea* (foxglove)
- *Geranium*
- *Hemerocallis* (day lily)
- *Hosta*
- *Hydrangea macrophylla* 'Lanarth White'
- *Iris laevigata*
- *Jasminum nudiflorum*
- *Leycesteria formosa*
- *Mahonia* x *media* 'Buckland'
- *Viburnum tinus* 'Eve Price'

*Anemone* x *hybrida* 'Honorine Jobert'

*Euphorbia characias*

*Iris sibirica* 'Perry's Blue'

*Malus* 'John Downie'

*Primula pulverulenta*

*Sambucus racemosa* 'Plumosa Aurea'

# Making the most of your soil *continued*

## Alkaline soil

**Advantages** Alkaline soil enables you to grow a wide range of plants; many vegetables (such as members of the cabbage family) will not grow as well in acidic soil. Ornamentals, such as clematis, are said to grow better in alkaline soil, and the finest rose gardens tend to be in alkaline areas. This soil suits earthworms; some pests and diseases, such as clubroot, are less of a problem.

**Disadvantages** There are certain plants that simply will not grow in alkaline conditions and, unfortunately, they are often among the most desirable. Rhododendrons, camellias, *Pieris*, some magnolias, and other woodland plants, such as *Uvularia* and *Trillium*, need the cool, moist, acidic soil associated with their native habitats. These plants are known as "calcifuges" or lime-haters. Some acid-loving plants may survive in alkaline soil but will look sick, with yellowing leaves (chlorosis). Alkaline soil tends to be deficient in manganese, boron, and phosphorus, all of which are important for healthy plant growth.

**Improving alkaline soil** You cannot, as such, improve alkaline soil, since a high pH can be both good and bad. Gardeners are advised to grow what suits their particular soil. Many acid-loving plants can be grown in containers, or in a raised bed filled with ericaceous (acidic) compost. Where the soil pH is neutral or just alkaline, years of adding organic matter may lower the pH enough for some smaller acid-loving plants.

### Plants for alkaline soil

- *Aquilegia* McKana Group
- *Aster* 'Coombe Fishacre'
- *Buddleja davidii* 'Dartmoor'
- *Buxus sempervirens*
- *Choisya ternata* Sundance
- *Clematis*
- *Cotoneaster horizontalis*
- *Erica carnea* 'Foxhollow'
- *Erysimum* 'Bowles Mauve'

- *Lavandula stoechas*
- *Mahonia* x *media* 'Buckland'
- *Nepeta* x *faassenii*
- *Phormium* 'Yellow Wave'
- *Primula vulgaris*
- *Pulsatilla vulgaris*
- roses
- *Salvia officinalis* 'Purpurascens'
- *Sedum* 'Herbstfreude'

*Alchemilla mollis*

*Campanula glomerata*

*Clematis cirrhosa*

*Cotinus coggygria* 'Royal Purple'

*Jasminum nudiflorum*

*Lonicera* (honeysuckle)

## Acidic soil

**Advantages** Some of the most spectacular garden plants, including rhododendrons, *Meconopsis*, and *Desfontainia*, will grow well only in acidic soil. Other species, such as *Hamamelis*, may survive in alkaline soil but simply perform better in acidic soil. Few garden plants will not tolerate mildly acidic soil, although a very low pH will limit your choices. Acidic soil is often associated with woodland conditions and tends to be cool and moist.

**Disadvantages** Acidic soil, though usually rich in organic matter, can be quite poor, especially if it is also sandy. To improve it, dig in plenty of well-rotted manure each year. Very peaty soil can, conversely, be waterlogged and require draining. This is often the most acidic of all and you may need to add lime to it for a range of plants to thrive. Most fruits and vegetables do not like strongly acidic soil and other plants simply will not grow—these are known as "calcicoles" or lime-lovers. Acidic soil is often deficient in phosphorus and may have too much manganese and aluminum for healthy plant growth.

**Improving acidic soil** If your soil is strongly acidic, you may need to increase the pH to broaden the range of plants you can grow. Adding spent mushroom compost is an excellent way of doing this. Powdered lime is an alternative. However, most gardeners usually feel that mildly acidic soil is desirable, and simply grow plants that enjoy their conditions.

### Plants for acidic soil

- *Astilboides tabularis*
- *Betula* (birch)
- *Camellia*
- *Cercis canadensis* 'Forest Pansy'
- *Cornus canadensis*
- *Corydalis flexuosa*
- *Daphne bholua* 'Jacqueline Postill'
- *Desfontainea spinosa*
- *Digitalis purpurea* (foxglove)
- *Hedychium densiflorum*
- *Leucothoe fontanesiana* 'Rainbow'
- *Meconopsis*
- *Photinia* x *fraseri* 'Red Robin'
- *Pieris*
- *Primula pulverulenta*
- *Rhododendron*
- *Romneya coulteri*

- *Uvularia grandiflora*

*Acer palmatum*

*Calluna vulgaris* 'Silver Knight'

*Carex elata* 'Aurea'

*Cornus kousa* var. *chinensis*

*Grevillea* 'Canberra Gem'

*Hydrangea quercifolia*

# Making a border

Flower and shrub borders provide color, scent, and seasonal interest, making them an essential part of the garden. Follow these basic steps when planning and preparing your borders to ensure their success through the year.

1 Decide where in the yard you want your border and mark out its shape. For a curved edge, use a garden hose. Make sure the border is not too narrow and that its shape fits well within the overall layout of the garden.

2 Using a half-moon edger or a small spade, carefully slice through the grass, following the contours of the hose. Make sure the cuts line up properly and push the full depth of the cutter into the ground.

3 With a spade, begin stripping off the sod. Cut it into manageable-sized squares from above, then slide the blade of the spade under the roots of the grass. Try to avoid removing an excessively deep layer of soil.

4 Stack the sod in a spare corner of the yard, grass side down. The soil in this sod is nutrient-rich and should be reused. After several months, the grass will die off and the pile can be cut up, sifted, and dug into the borders.

# Making a border *continued*

5 Dig over the exposed soil with a fork, pushing the tines down to their full depth. Remove old roots, large stones, and debris that you unearth, and break up large clods of soil. Work the soil until it has a crumbly texture.

6 With a spade, spread about 2 in (5 cm) of organic matter, such as well-rotted farmyard manure or garden compost, over the surface of the border. Turn the compost into the soil, and mix it in evenly.

7 If the soil is heavy or poorly drained, spread a 3-in (8-cm) layer of coarse sand or gravel over it, and dig this into the top 6 in (15 cm) of soil with a spade. This will help open up drainage channels through the soil in the root zone.

8 Using a soil rake, remove any remaining stones, roots, or debris that may have worked their way up to the surface. Then, with the flat back of the rake, carefully level off any mounds and hollows.

9 Set out the plants, still in their pots, on the ground, adjusting their positions until you are happy. Pay attention to their eventual size, flower and foliage color, and season of interest to achieve your desired effect.

## Tip for success

To stop soil from spilling out onto the lawn, consider adding edging to the front of the border before planting. Use a level to make sure the edging is level.

# Finishing touches

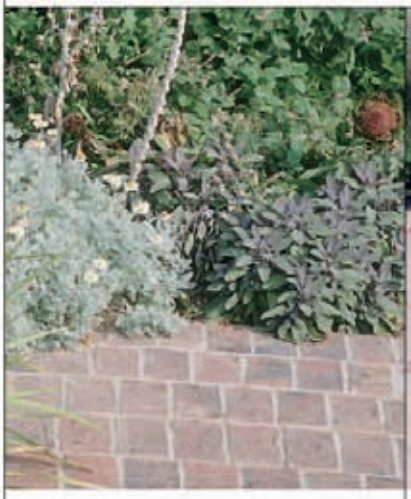
To help set off planting and add a touch of "polish" to the garden, small additions, such as edgings and mulches, can make a big impact.

## Soft lawn edging

It is surprising how much difference a well-edged lawn makes to the overall look of a garden. Where borders meet grass, trim with edging shears after mowing to maintain the shape of the lawn. Edging irons are also useful for reshaping when required. Plants that spill from borders onto the lawn may add a touch of informality, but will damage the lawn in the long run.

## Choosing a hard edge

Borders that meet hard landscaping materials require less maintenance than soft edging. Sprawling plants are best grown next to hard surfaces where the border's shape can be maintained more easily. Use paving for formal or informal situations, and areas where grass struggles to grow, such as in shade or next to narrow paths.



**Brick edging** Laid as a path or in a single row between a border and lawn, or along gravel paths, bricks create a traditional feel. They also blend well with plantings.

**Paved edging** Where paving meets a border, attractive informal effects can be achieved. Allow plants, such as lavender, to billow out from flower beds, softening the hard layout.

**Wood edging** If you have border soil to retain, wood edging is an easy-to-install option. Partially conceal with plantings to help it blend in, and apply wood preservative to prevent rotting.

## The benefits of mulching

Mulches help to conserve soil moisture, reduce weeding, and provide a decorative element, and some add organic matter to soil, improving its fertility and promoting plant growth. A mulch is simply a layer of material spread over the soil surface, and different situations and plantings require different types. Avoid applying them too thickly—about 1¼ in (3 cm) is ideal—or over the crowns of plants. Mulches are usually applied in early spring.

**Organic matter** Garden compost or well-rotted manure is an ideal mulch because it aids plant growth, improves the soil, and helps retain moisture. It needs to be reapplied every year.

**Cocoa shells** Lightweight and easy to apply, cocoa shells break down, enriching the soil. They are, however, easily disturbed by wind, animals, or birds, and can look unsightly.

**Gravel** Long-lasting and inexpensive, gravel preserves moisture in summer and keeps standing water away from sensitive plants, such as alpines, in the winter. It is heavy to apply.

**Decorative mulches** Colored glass chips, crushed seashells, and other decorative mulches are ideal for pots and containers. They will reduce weeds and conserve moisture.

**Weed membranes** Laid beneath mulches before planting, porous membranes drastically reduce weeds. Adding plants after a membrane has been laid can be tricky, though.

**Bark chips** Lightweight, organic, and weed-suppressing, bark chips are a popular mulch, but as they slowly break down, they may remove valuable nitrogen from the soil.

# Making your own compost

Making compost from your kitchen and garden waste is a sustainable and environmentally friendly way of recycling. Applied as a mulch, compost helps to improve the fertility and moisture-retaining qualities of your soil.

**Types of composters** The basic way of making compost is to pile it into a heap, but this can be unsightly, and better compost is often achieved more quickly using a composter. The simplest structures are bays, usually made of corrugated plastic or metal, in which waste is piled. Wooden compost bins are easier on the eye, and can be built at home from scrap wood; otherwise you can buy ready-made bins, often with slatted sides or vents for air circulation. Effective and inexpensive, lightweight plastic compost bins (*right*) are also a popular choice.

**Filling your bin** Almost any vegetable matter can be added to a compost bin, and the more diverse the range of materials, the better the compost. It is also important to keep woody and nitrogen-rich leafy materials in proportion: you should try to include about twice as much woody material (twigs, paper) as nitrogen rich-material (grass, kitchen scraps). Mix grass cuttings with woodier clippings or even shredded paper, because a thick layer of grass will inhibit important air movement. Chop bigger cuttings into small pieces and avoid adding weeds with seeds, or persistent perennial weeds. Place a layer of coarser twigs in the bottom of the bin and then add the material in layers. Spread a little farmyard manure between layers to help speed up the composting process.

Leafy material adds nitrogen and moisture:
- Grass cuttings and weeds
- Kitchen vegetable waste
- Fallen leaves
- Herbaceous plant clippings
- Sappy hedge trimmings
- Windfall fruit
- Old bedding plant material

Woody, carbon-rich material improves airflow:
- Woody plant clippings and twigs
- Shredded paper
- Scraps of cardboard
- Untreated wood shavings
- Stems of herbaceous plants
- Bark mulch

Layer woody and leafy material in your compost pile.

**Speeding up composting** Nitrogen-rich manure contains microorganisms that promote composting, so add it to your pile to help the material break down more quickly. Alternatively, you can buy special compost additives. Turning the pile also improves air circulation, speeds up rotting, and ensures that all the material is composted.

## Tip for success

Too much wet, green, nitrogen-rich material, such as grass cuttings, will quickly turn the compost pile sour and smelly. Mix it with coarser woody matter in layers, and aim to turn the pile regularly.

# Planting a perennial

Perennials are plants that grow from year to year, and many are long-lived. But for these plants to perform well as they mature, they must be planted and established with care.

1 Place the plant in its pot on the ground in a position that suits its growing needs and not too close to other plants. The soil in the pot should be thoroughly soaked before planting to help give the plant a good start.

2 With a spade, dig a hole wider and deeper than the size of the plant's container. Add organic matter, such as garden compost, to the base of the hole and dig it in well. Pour some water into the hole before planting.

3 Remove the plant carefully from its pot. If the roots tightly encircle the root ball, the plant is pot-bound and the roots need to be teased out gently. Place the plant in the hole, slightly deeper in the ground than when it was in its pot.

4 Backfill around the root ball, firming the soil as you go and ensuring that the plant stands straight in its hole. Avoid mounding the soil around the stems; the plant should be in the center of a shallow depression. Water well.

# Planting a tree

Planting a tree may seem a simple task, but these plants are long-lived and should be planted well and given the appropriate aftercare if they are to fulfill their potential in years to come.

1 Soak the root ball of the tree in its container before planting. This will compensate for any water loss from the roots during the planting process and ensure that the tree settles into its position well.

2 With a spade, dig a planting hole about three times as wide as the diameter of the pot and 12 in (30 cm) deep (most root activity takes place in the top layer of soil). Lightly fork the base and sides of the hole.

3 Check the depth by putting the pot in the hole and placing a pole across the top—it should rest on both sides of the hole and on the top of the root ball. You may need to add or remove soil in the hole.

4 Gently remove the root ball from its pot—the pot should slide off easily, leaving the root ball intact. Carefully tease out some of the larger encircling roots, to help the tree root into the surrounding ground more successfully.

# Planting a tree *continued*

5 Stand the tree in its final position. Drive a sturdy stake into the ground close to the tree trunk and at a 45° angle over the root ball, to avoid damaging the roots. Make sure that the stake faces into the prevailing wind.

6 Backfill the hole with soil, working it in around the roots. Unless the soil is poor or sandy, do not add organic matter because this seems to prevent the roots from spreading out in search of nutrients. Firm the soil in gently.

7 Tie the tree quite loosely to the stake with a tree tie, about 18 in (45 cm) from the ground, to allow the stem to flex in the wind. Check the tie regularly and loosen it as the tree girth expands, to prevent damage to the bark.

8 Water the tree well after planting and during dry periods for the first couple of seasons. Add a mulch of well-rotted garden compost, about 3 in (8 cm) deep, around the tree. Keep the mulch about 6 in (15 cm) away from the trunk.

9 Over the next two to three years, use sharp pruners to remove any damaged wood or branches that spoil the tree's shape, such as crossing, rubbing branches. Do not leave stumps—cut fairly close to the main stem.

# Planting a shrub

Shrubs form the backbone of a planting scheme, providing important structure as well as flower and foliage effects. Before planting, check the plant label for the shrub's preferred site and soil, since moving it at a later date will be difficult.

## Tip for success

Once planted, apply a top-dressing of fertilizer above the roots in spring. Later watering or rain will wash it down.

1 Soak the plant thoroughly in its pot. With a spade, dig a large hole, approximately two to three times the diameter of the pot. Remove any old roots and large stones, and break up the soil in the base of the hole with a fork.

2 To check that the hole is the correct depth, place a pole across the top; it should rest on both sides of the hole and on the top of the root ball. Position the plant with its best side facing the direction from which it will be viewed.

3 Remove the pot; it should slide off easily, leaving the root ball intact. Tease out any encircling roots. Add organic matter, such as garden compost, to the removed soil, especially if it is poor. Backfill around the root ball.

4 Firm the soil down gently. The plant should sit at the center of a shallow depression, which will assist watering. Spread a mulch of organic matter around the plant, keeping it away from the stems. Water the plant well.

# Planting a climber

Climbing plants are particularly useful in small gardens because they add height without too much bulk, maximizing the use of limited space. They are also a quick and effective way of covering dull fences and garden structures.

## Tip for success

A system of vine eyes threaded with wire along a fence is perhaps the simplest and least visible way of providing support for climbers. The system is easy to attach and allows plants to grow to their full potential.

1 Dig a hole twice the diameter of the root ball, 12–16 in (30–40 cm) from the fence. To support the stems and achieve good initial coverage, construct a fan from canes pushed into the soil and angled toward the fence.

2 Make sure the plant is well watered, then position it in the hole at an angle pointing toward the fence. Carefully remove the pot and any supporting stakes. Separate multiple stems growing from the base of the plant.

3 Backfill the hole with the removed soil mixed with some organic matter, such as garden compost. Firm the soil gently as you go. The plant should be at the center of a shallow depression, to aid watering and establishment.

4 Select the stems to be trained up the canes, tying in one to two stems per cane with gardener's twine. Spread a mulch of bark chips or organic matter over the soil to keep in the moisture and suppress weeds.

# Sowing annuals outside

Many hardy annuals, such as California poppies (*Eschscholzia*), are best sown *in situ* outside, avoiding the root disturbance that occurs when seedlings are removed from their pots. Plants grow quickly to give fine summer displays.

## Tip for success

The fine soil of a seedbed is attractive to cats, and young seedlings may be disturbed by birds. To avoid these problems, protect the area with twiggy sticks pushed into the ground.

1 Select an open area without any competing plants for sowing the seeds. Lightly fork over the soil, breaking up large clods, and then remove large stones, weeds, and debris with a rake. Work the soil into a fine, level tilth.

2 Make drills (shallow depressions to sow seed into) in the soil by pushing a pole or bamboo cane into the soil surface. Drills make it easier to identify seedlings; weed seedlings are unlikely to emerge in straight lines.

3 Place the seeds into the palm of your hand, and aim to pour the seed gently from a crease as you pass your hand along the drill. Do not sow the seed too thickly. Larger seeds can be placed in the drill with your fingertips.

4 Lightly cover the drills with fine soil and water well using a can with a fine spray to avoid disturbing the seeds. Keep the seedbed moist and remove any weeds. When the seedlings emerge, carefully thin out close-growing plants.

# Sowing hardy annuals

While many hardy annuals can be sown outside *in situ*, it is often safer and more rewarding to plant seeds in pots under cover, in a cold frame, a greenhouse, or on a sunny windowsill.

**Tip for success**

Always label your seeds using a waterproof pen. Include the name of the plant and the date of sowing.

1 Fill a clean or new 3½-in (9-cm) pot with a good-quality seed-sowing potting mix, leaving a ¾–1¼-in (2–3-cm) gap beneath the rim of the pot. Firm the soil gently to create an even surface for the seeds.

2 Using a watering can with a fine spray, dampen the potting mix, being careful not to disturb it by splashing too much. Alternatively, stand the pots in a tray of water until the surface is moist, then remove.

3 Sow the seed evenly. Large seeds are easy to position, but fine seeds should be spread from the palm of the hand. Some seeds need to be covered by a fine layer of soil or vermiculite; follow the instructions on the seed packet.

4 When the seeds have germinated and produced a few sets of leaves, harden them off by placing the pots outside during the day for a few weeks. Then you can plant them out in the garden.

# Sun-baked gravel garden

In a sunny corner, a gravel garden offers the chance to grow an interesting range of plants: herbs with aromatic leaves, plants with silvery foliage, alpines, and some grasses are good choices. These plants enjoy growing through gravel because it keeps excessive moisture away from their stems, yet helps to keep the roots cool and moist. Gravel also warms up quickly during the day and retains warmth at night.

## Border basics

**Size** 10 x 6 ft (3 x 2 m)
**Suits** Herbs, low-growing plants, annuals, bulbs, gray-leaved plants
**Soil** Well-drained, poor soils
**Site** Open and sunny, not too exposed

## Shopping list

- 2 x *Parahebe perfoliata*
- 1 x *Helictotrichon sempervirens*
- 1 x *Thymus pulegioides* 'Bertram Anderson'
- 1 x *Santolina chamaecyparissus*
- 1 x *Aurinia saxatilis* 'Variegata'
- 1 x *Rosmarinus officinalis* Prostratus Group

## Planting and aftercare

Dig over the site, removing large stones, debris, and weeds; spot-treat perennial weeds like bindweed, because they will be hard to remove once gravel is spread. Add organic matter, such as well-rotted garden compost, to the soil, and dig in plenty of gravel to at least a spade's depth to help provide good drainage.

Place any feature rocks or driftwood as focal points. Position plants with plenty of space between each one. Add sand to the planting holes and place plants slightly higher than the soil surface. As you spread the gravel, work some into the crowns of plants. Water well. Once settled, the plants will need watering only in the driest periods.

*Parahebe perfoliata*

*Helictotrichon sempervirens*

*Thymus pulegioides* 'Bertram Anderson'

*Santolina chamaecyparissus*

*Aurinia saxatilis* 'Variegata'

*Rosmarinus officinalis* Prostratus Group

# Cottage garden medley

This ever-popular, typically English style of planting uses mainly herbaceous flowering plants in a relaxed, informal way. The flowers are usually pale pastel colors with a few brighter hues added as highlights. Traditional cottage garden favorites include delphiniums, foxgloves (*Digitalis*), verbascums, and penstemons, as well as woody plants such as roses and lavender (*Lavandula*). Although not low-maintenance, such planting schemes are certainly beautiful in summer, when the plants all bloom together in profusion.

## Border basics

**Size** 6 x 5 ft (2 x 1.5 m)
**Suits** A mixture of herbaceous perennials
**Soil** Well drained
**Site** Sunny with some shelter from wind

## Shopping list

- 3 x *Delphinium grandiflorum* 'Summer Blues'
- 3 x *Verbascum* x *hybridum* 'Snow Maiden'
- 3 x *Delphinium* 'New Zealand Hybrids'
- 3 x *Geum* 'Blazing Sunset'
- 3 x *Penstemon digitalis* 'Husker Red'
- 3 x *Digitalis purpurea*

## Planting and aftercare

Prepare the border before planting, adding well-rotted farmyard manure. Check that drainage is good; if not, add some gravel. Planting in spring is best for perennials. Three of each plant will guarantee a decent show of flowers in the first year, and odd numbers of plants look best in informal plantings. Plant in small drifts, with taller plants positioned toward the back, but do not be too rigid about this—the effect should appear relaxed. The delphiniums, in particular, may need staking with canes. In fall after flowering or the following spring, cut down old foliage, and mulch with manure.

*Delphinium grandiflorum* 'Summer Blues' ❄❄❄ ◑ ☼

*Verbascum* x *hybridum* 'Snow Maiden' ❄❄❄ ◊ ☼

*Delphinium* New Zealand Hybrids ❄❄❄ ◑ ☼

*Geum* 'Blazing Sunset' ❄❄❄ ◑ ◊ ☼

*Penstemon digitalis* 'Husker Red' ❄❄ ◑ ◊ ☼

# Foliage effects

Raised beds are easy to maintain and can be constructed almost anywhere. For a contemporary look, planting should be colorful and stylish, and provide year-round interest. Pick plants that complement each other in a range of colors and textures—here, much of the interest is provided by foliage.

## Bed basics

**Size** 3 x 3 ft (1 x 1 m)

**Suits** A range of nonvigorous plants with similar requirements

**Soil** Moist but well drained

**Site** Sunny, and sheltered from strong, drying winds

## Shopping list

- 1 x *Euphorbia amygdaloides* 'Purpurea'
- 1 x *Sedum spectabile*
- 1 x *Carex comans* 'Frosted Curls' or *Molinia caerulea* subsp. *caerulea* 'Variegata'
- 3 x *Ophiopogon planiscapus* 'Nigrescens'
- 1 x *Heuchera* 'Plum Pudding'

## Planting and aftercare

Any raised bed must have adequate drainage holes; without them the plants will rot. A layer of crocks or polystyrene at the base will help water to run away freely. In a small bed, use a soil-based potting mix blended with some organic matter, such as well-rotted manure; a large bed should be filled with good-quality topsoil with some well-rotted garden compost worked into it. Leave the bed for a few days to let the soil settle. Position shorter plants, such as the *Ophiopogon*, at the edges, and taller plants, like the *Euphorbia*, in the center of the bed. Water well. Make sure that the soil never dries out, weed the bed regularly, and cut down any faded herbaceous growth, such as the *Sedum* flowerheads, in fall.

*Euphorbia amygdaloides* 'Purpurea'

*Sedum spectabile*

*Carex comans* 'Frosted Curls'

*Ophiopogon planiscapus* 'Nigrescens'

*Heuchera* 'Plum Pudding'

Alternative plant idea

*Molinia caerulea* subsp. *caerulea* 'Variegata'

# Tree and shrub combination

Trees and shrubs can be used to create exciting combinations for beds and borders. They also tend to require less maintenance than herbaceous plants, and retain structure and sometimes foliage over winter. Include a range of growth habits and sizes, foliage color and texture, plants with attractive flowers and others with winter interest, all of which will thrive in the given conditions.

## Border basics

**Size** 10 x 8 ft (3 x 2.5 m)
**Suits** Wide range of shrubs and small trees; compact selections are best
**Soil** Acidic, free-draining, moisture-retentive soil
**Site** Sunny and sheltered

## Shopping list

- 1 x *Aucuba japonica* 'Picturata'
- 1 x *Cotinus* 'Grace'
- 1 x *Phormium tenax* 'Atropurpureum'
- 1 x *Grevillea juniperina*
- 1 x *Magnolia grandiflora* 'Goliath'
- 1 x *Pittosporum tobira* 'Nanum'

## Planting and aftercare

Dig the soil thoroughly, adding plenty of rotted garden compost. Space plants out well because they will be difficult to move when larger. The biggest plant is likely to be the magnolia, so put it at the back of the border. The evergreen gold-splashed foliage of the *Aucuba* is a focal point, so position the plant centrally. Its rounded form contrasts well with the spiky *Phormium*. The lower-growing *Pittosporum* and *Grevillea* (which needs acidic soil) can be placed at the front. The *Cotinus* balances the composition, its purple leaves matching those of the *Phormium*. Make sure all are well watered and firmed in at planting. Some pruning, especially of the *Grevillea* and *Cotinus*, may be required later, to stop them from outgrowing their positions.

*Aucuba japonica* 'Picturata'

*Cotinus* 'Grace'

*Phormium tenax* 'Atropurpureum'

*Grevillea juniperina*

*Magnolia grandiflora* 'Goliath'

*Pittosporum tobira* 'Nanum'

# Spring hot spot

Vibrant, fiery colors are not solely for late summer; there are various perennials and bulbs that provide similar hues in late spring, although the effect is different. The reds, oranges, and yellows of plants such as tulips, the first lupines, *Doronicum*, and *Euphorbia* can be combined with verdant new growth to create a glowing display.

These hot color combinations contrast with the whites, blues, and cool yellows found in abundance elsewhere at this time, making a dazzling display.

## Border basics

**Size** 6 x 6 ft (2 x 2 m)
**Suits** Early-flowering perennials, bulbs (especially tulips), perennials with attractive young foliage
**Soil** Any fertile and moist soil
**Site** Sheltered with some direct sun

## Shopping list

- 20 x *Tulipa* 'Ballerina'
- 20 x tulips of contrasting shape
- 5 x *Polygonatum* x *hybridum*
- 5 x *Euphorbia griffithii* 'Fireglow'
- 5 x *Foeniculum vulgare* 'Purpureum' (just visible)

## Planting and aftercare

Prepare the border by adding plenty of organic matter, such as garden compost, to the soil. Position the perennials first, with the tallest plant, Solomon's seal (*Polygonatum*), toward the back. Interplant the *Euphorbia* with the bronze fennel (*Foeniculum*), leaving reasonable spaces in between to allow planting pockets for the tulips. Plant the bulbs at three times their depth, in eight groups of five. Avoid mixing the tulip cultivars because this will dilute the effect.

The *Euphorbia*, in particular, will suffer if the soil becomes too dry. Watch out for sawfly larvae on the Solomon's seal.

*Tulipa* 'Ballerina'

*Polygonatum* x *hybridum*

*Tulipa* (pinky red)

*Euphorbia griffithii* 'Fireglow'

# Lush leaves for shade

In a shaded courtyard or corner of a terrace, a modern planting scheme in a raised bed can create a dramatic, rather exotic effect. Many foliage plants grow well in some shade, and a mix of evergreen shrubs and herbaceous plants provides year-round interest. A tall bamboo (*Phyllostachys*) will catch the breeze, adding a dynamic element to the planting, while a few variegated plants, such as hostas, help lift the planting out of the shadows, as will painting the backdrop and raised walls a pale color.

## Border basics

**Size** 8 x 5 ft (2.5 x 1.5 m)
**Suits** Lush foliage plants
**Soil** Fertile and moisture-retentive
**Site** Sheltered, semi-shaded corner

## Shopping list

- 2 x *Hosta* 'Francee'
- 1 x *Hebe salicifolia*
- 3 x *Fatsia japonica*
- 1 x *Phyllostachys nigra*
- 1 x *Miscanthus sinensis* 'Variegatus'
- 3 x *Ophiopogon planiscapus* 'Nigrescens'
- 2 x *Hedera helix* (ivies)

## Planting and aftercare

Make sure the bed has enough drainage holes to prevent waterlogging. Choose a good quality topsoil and add well-rotted manure to it before planting. Position taller plants at the back (the bamboo will look best in the corner). The hostas, *Ophiopogon*, and ivies should go at the front. Contrast the hand-shaped foliage of the *Fatsia* with the white-edged blades of the *Miscanthus*. Spread white or gray pebbles as a mulch over the soil, and water the plants in well, ensuring they are not short of water while establishing. Aftercare is easy: cut down old herbaceous growth in late fall or spring, and watch out for slugs.

*Hosta* 'Francee'

*Hebe salicifolia*

*Fatsia japonica*

*Phyllostachys nigra*

*Miscanthus sinensis* 'Variegatus'

*Ophiopogon planiscapus* 'Nigrescens'

# Formal front yard

Small front yards lend themselves to formal planting. Traditionally, these designs feature a low perimeter wall of clipped boxwood (*Buxus*) hedges in a simple shape, such as a square, filled with a mixture of brightly colored foliage and flowering plants, some tender, others perennials. There is often a central "dot plant," such as a *Cordyline*, to serve as a focal point. Any bare soil is then mulched with a layer of gravel. This helps to reduce weeding and keeps the garden looking neat.

## Border basics

**Size** 5 x 5 ft (1.5 x 1.5 m)
**Suits** Boxwood hedges, bright tender perennials, colorful hardy plants
**Soil** Ideally, fertile, well drained, and not too dry
**Site** Small, formal situation, preferably with some sun

## Shopping list

- 5 x *Pelargonium* (red)
- 3 x *Deschampsia flexuosa* 'Tatra Gold'
- 2 x *Phormium* 'Tom Thumb'
- 1 x *Penstemon digitalis* 'Husker Red'
- *Buxus sempervirens* (enough to make a border)
- 3 x *Spiraea japonica* 'White Gold'

## Planting and aftercare

Dig over the site, removing any weeds, and add well-rotted organic matter, such as manure. Firm and level the soil with a rake. Plant the boxwood plants first, 6–8 in (15–20 cm) apart, to form the framework of your design. Then arrange the remaining plants in bands of color. The border will need regular upkeep to keep it looking immaculate. Deadhead the pelargonium throughout the season; in early summer, trim the boxwood and, if required, the spiraea. In spring, replace the tender pelargoniums and reduce the flowering stems of the penstemons.

*Pelargonium* (red)

*Deschampsia flexuosa* 'Tatra Gold'

*Phormium* 'Tom Thumb'

*Penstemon digitalis* 'Husker Red'

*Buxus sempervirens*

*Spiraea japonica* 'White Gold'

# Mediterranean moods

Choose the sunniest spot in the garden, away from cold winds, and select plants reminiscent of Mediterranean vacations: irises, grasses, euphorbias, and evergreen shrubs, such as olearia. Add herbs, like rosemary or sage, and bright-flowered bulbs, such as alliums. Terra-cotta pots planted with more tender species, such as succulent agaves, will help reinforce the Mediterranean feel.

## Border basics

**Size** 10 x 10 ft (3 x 3 m)

**Suits** Grasses, neat evergreen shrubs, irises, bulbs, herbs, succulents, semi-tender plants

**Soil** Any free-draining

**Site** Sunny and sheltered, ideally by a wall

## Shopping list

- 3 x *Iris* 'Jane Phillips'
- 1 x *Olearia* x *haastii*
- 3 x *Euphorbia characias* subsp. *wulfenii*
- 5 x *Allium hollandicum* 'Purple Sensation'
- 1 x *Anemanthele lessoniana* (*Stipa arundinacea*)
- 1 x *Bergenia cordifolia*
- 2 x *Ballota pseudodictamnus*

## Planting and aftercare

Dig over the soil, removing any stones and weeds, and add plenty of organic matter, such as manure. If the site is not well drained, dig in gravel. Set taller plants at the back of the border, at least 12 in (30 cm) from the base of the wall. Plant shrubs and perennials first; bulbs are best planted in drifts around the key plants later. The iris rhizomes should be near the soil surface, so that they are partially exposed. Mulch with gravel and water well.

Remove the flowering stems of irises after the blooms have faded. In spring, cut out the previous year's flowering stems of euphorbias as close to the base as possible, avoiding the toxic sap.

*Iris* 'Jane Phillips'

❄❄❄ 💧 ☼

*Olearia* x *haastii*

❄❄❄ 💧 ☼

*Euphorbia characias* subsp. *wulfenii*
❄❄❄ 💧 ☼

*Allium hollandicum* 'Purple Sensation' ❄❄❄ 💧 ☼

*Anemanthele lessoniana*
❄❄ 💧 ☼

# Mixed herb tapestry

Well-planted herb borders should delight the senses: not only are they attractive to look at, but the aroma of foliage and flowers provides an extra element of interest, and some herbs can also be used to flavor food. Many have variegated or silver leaves, so they are still attractive when out of flower. Try also to include some evergreen herbs, such as lavender (*Lavandula*) or rosemary (*Rosmarinus*).

## Border basics

**Size** 6 x 6 ft (2 x 2 m)
**Suits** Culinary herbs, such as thyme, oregano, marjoram, sage, chives, rosemary, and also those with more medicinal properties, such as lavender and feverfew
**Soil** Any well-drained, fairly poor soil
**Site** An open site in sun, but not too exposed to cold

## Shopping list

- 10 x *Origanum vulgare* 'Polyphant'
- 5 x *Lavandula angustifolia* 'Twickel Purple' or *Salvia officinalis* 'Icterina'
- 10 x *Thymus doerfleri* 'Doone Valley'
- 10 x *Thymus* x *citriodorus*
- 10 x *Origanum vulgare* 'Aureum'

## Planting and aftercare

Try adopting a formal pattern with the plants, as in the style of a simple knot garden. The plants can be positioned in rows or bands, where they will knit together well. The lavender is the tallest plant and should go at the back, or in the center if the bed is circular; the variegated sage *Salvia officinalis* 'Icterina' could be used as a culinary alternative. Next, plant contrasting bands of the smaller herbs.

A gravel mulch placed over the soil after planting helps to suppress weeds and keeps moisture away from the crowns of the plants.

*Origanum vulgare* 'Polyphant'
❄❄❄ 💧 ☼

*Lavandula angustifolia* 'Twickel Purple' ❄❄❄ 💧 ☼

*Thymus doerfleri* 'Doone Valley'
❄❄❄ 💧 ☼

*Thymus* x *citriodorus*
❄❄❄ 💧 ☼

*Origanum vulgare* 'Aureum'
❄❄❄ 💧 ☼

Alternative plant idea

*Salvia officinalis* 'Icterina'
❄❄ 💧 ☼

# Fall elegance

A border designed for a fine fall scheme can make a great addition to the garden. After the dazzling displays of summer, this is a forgotten season in many gardens, and yet there are many plants that are at their best at this time. Certain grasses and various other late-performing perennials, such as *Sedum*, *Aster*, *Salvia*, *Kniphofia*, and *Verbena*, can be combined with the seedheads of plants that flowered in summer, perhaps set against the vivid autumnal hues of deciduous shrubs and trees.

## Border basics

**Size** 10 x 10 ft (3 x 3 m)
**Suits** Late-flowering perennials, grasses, and plants with ornamental seedheads or berries
**Soil** Any well-drained, fertile soil
**Site** An open site in sun, not too exposed

## Shopping list

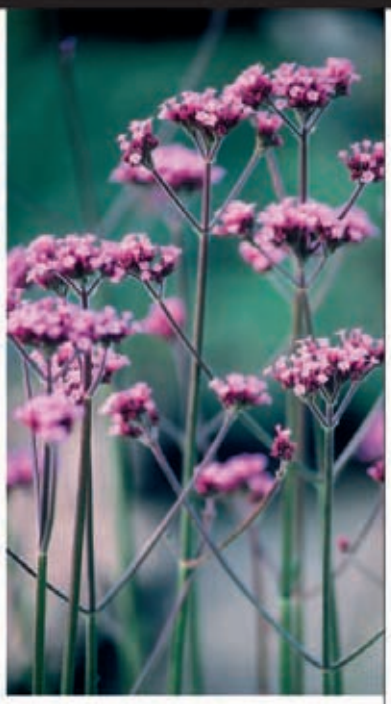
- 3 x *Stipa gigantea*
- 7 x *Verbena bonariensis*
- 7 x *Sedum* 'Herbstfreude'
- 5 x *Calamagrostis brachytricha*
- 3 x *Perovskia* 'Blue Spire'

## Planting and aftercare

For this scheme, it is better to plant in sweeps rather than groups for a more flowing effect. The *Stipa* is the tallest plant, so place it toward the back. In front, plant the dainty *Perovskia* and upright *Calamagrostis*. This grass flowers earlier in the season, but in fall the seedheads are an attractive rich brown. Allow the grass to mingle with the *Sedum*, best planted toward the front in a broad sweep, providing contrast and intense color. Dot the slender *Verbena* throughout because its transparent form provides no visual barrier.

Retain the seedheads of these plants for as long as possible, cutting down in spring before new growth begins.

*Stipa gigantea*



*Verbena bonariensis*

*Sedum* 'Herbstfreude'

*Calamagrostis brachytricha*

# Winter blaze

Although winter is the season of snow and ice, there is still plenty to see in the garden if you include plants that provide seemingly unseasonal color. The stems of some deciduous shrubs, such as *Cornus* and *Salix*, are brightly hued, and the foliage of many conifers intensifies in color as low temperatures bite. A few plants produce showy flowers during this season, in particular winter heathers (*Erica*), but also bulbs such as snowdrops (*Galanthus*) and winter aconites (*Aconitum*).

## Border basics

**Size** 10 x 10 ft (3 x 3 m)
**Suits** A range of winter-interest plants
**Soil** Reasonably well drained and not too dry
**Site** Somewhere open that catches the winter sun

## Shopping list

- 1 x *Chamaecyparis lawsoniana* 'Elwoodii'
- 9 x *Erica* x *darleyensis* 'Archie Graham'
- 5 x *Cornus sanguinea* 'Winter Beauty'
- 1 x *Pinus sylvestris* Aurea Group
- 7 x white *Erica carnea*

## Planting and aftercare

Position the *Chamaecyparis* toward the back of the border—it will serve as a fine foil for the brighter colors. The golden pine (*Pinus*) should also be toward the back, in front of the *Chamaecyparis*. Plant the *Cornus* in a drift, mostly in the middle of the border, edging toward the front. Underplant with the heathers, creating strokes of color. Do not intermingle the colors.

The best stem color from the *Cornus* is found on young growth, so after a couple of years, cut out one-third of old stems from each plant annually in spring. Trim the winter heathers with shears after they have flowered.

*Chamaecyparis lawsoniana* 'Elwoodii' ❄❄❄ ◑ ◊ ☼

*Erica* x *darleyensis* 'Archie Graham' ❄❄❄ ◑ ◊ ☼

*Cornus sanguinea* 'Winter Beauty' ❄❄❄ ◑ ☼

*Pinus sylvestris* Aurea Group ❄❄❄ ◑ ◊ ☼

# Choosing a container

When selecting pots and containers from the wide range available at garden centers, there are some key factors to take into account before you buy. As well as choosing a style, shape, and color that suits your garden design, also consider the material from which the container is made, since each has its pros and cons.

## Clay pots

Clay pots may be glazed or unglazed, colored or patterned, light or dark in color. Orange terra cotta brings a taste of the Mediterranean to the garden.

**Advantages** They are attractive to look at, and can make a long-lasting addition to the garden, often improving with age and wear. There is a clay pot for most situations, and they can be very good buys.

**Disadvantages** Many clay pots are not fully frost-proof and are prone to winter damage. They are also best avoided in exposed sites because they are easily broken. Fired clay is a porous material, so plants can dry out quickly, especially in summer, and moving these containers can be hard work since they are often heavy.

## Metal containers

Containers made of metal may seem like a contemporary idea, but in fact some of the most desirable antique pots are lead, and suitable for a range of situations. Modern metal containers tend to be made of steel or galvanized aluminum and are simply styled, unlike lead planters, which feature more elaborate, classical designs.

**Advantages** By nature, metal containers are long-lasting, and can be heavy (especially lead ones), which makes them good for open sites. They can also be very stylish.

**Disadvantages** Metal containers can be expensive, particularly those made of lead; these are also exceptionally heavy. They also usually look out of place in an informal garden and may not suit some plants.

## Wooden containers

Wood is a good material for a planter; it is soft and easily shaped, weathers well if treated with preservative, and suits a range of situations. It is also hard-wearing and can tolerate rough treatment.

**Advantages** Although fairly lightweight and therefore easily moved, wooden containers are strong and durable. They are also most attractive and a good choice for situations where large planters are required.

**Disadvantages** Good-quality wooden containers can be quite expensive, especially those suited to more formal sites. They also need regular treatment with preservative to keep them looking good. Make sure they are made from sustainably harvested lumber.

## Stone containers

Pots and containers made of stone make beautiful ornamental planters. Granite containers can be used to give a Japanese feel, while old stone troughs suit alpines and other small plants.

**Advantages** Stone containers are very heavy, so not easily stolen or blown over, and long-lasting. Stone also looks good and gives a feel of permanence, especially once it has become colonized with mosses and lichens.

**Disadvantages** Genuine stone containers are very expensive, antique ones especially so, and you may feel that a concrete alternative is better value. The weight of stone must also be considered when transporting the pot and maneuvering it into place in the garden.

## Synthetic pots

Plastic has long been used as a material for pots, and it may be disguised to look like clay, wood, or stone, although not always very convincingly. Increasingly, resins and other new materials are being used instead of plastic.

**Advantages** Synthetic pots are generally lightweight and easy to handle and transport. They tend to be tougher and more durable (and frost-resistant) than clay, and are far cheaper than stone or lead alternatives.

**Disadvantages** Synthetic pots lack the charm of traditional materials: an authentic stone, lead, or even clay planter feels more characterful than one made of plastic. Synthetic pots do not age well and may have a short life span. Being light, they are easily blown over.

# Plant a colorful container

One of the simplest ways of injecting seasonal interest into your garden is to plant up a few pots. Follow these easy guidelines to help ensure that your displays are attractive and long-lasting.

1 Before you plant the container, add water-retaining crystals to the potting mix. These swell up once moist, and provide plants with an extra reservoir of water, which helps to ensure plants do not suffer in dry spells.

2 Arrange your selected plants in their original pots in the container to see how they look—this way, adjustments can be easily made. When you are satisfied, remove the plants from their pots and plant the container.

3 Fill around the plants with potting mix when they are in their final positions, leaving a 2-in (5-cm) gap between the top of the soil and the rim of the container to allow for easy watering and a gravel mulch.

4 Spread a ¾-in- (2-cm-) deep gravel mulch over the top of the soil to help to conserve moisture in summer, deter weeds, and prevent unsightly soil splash when watering. It also makes an attractive finish to the planting.

# Spring selection

Few plants are a more welcome sight than spring-flowering bulbs, and most are easy to grow and care for. These versatile plants are wonderful for pots and window boxes or for planting out in the garden, and they can be treated as permanent plantings or simply discarded after flowering. A good selection should provide color over a long period, from the first snowdrops in late winter to the last tulips in early summer. Try planting the same types of bulbs together in pots and grouping them, or mix them.

## Container basics

**Size** Approx. 6-in- (15-cm-) diameter terra-cotta pots
**Suits** Potted flowering bulbs
**Potting mix** Free-draining
**Site** Sunny, not too exposed

## Shopping list

- 6 x *Hyacinthus orientalis* 'Ostara'
- 12 x *Narcissus* 'Sweetness'
- 10 x *Iris winogradowii*
- 12 x *Iris reticulata*
- 6 x *Iris* 'Katharine Hodgkin' or *Muscari armeniacum*

## Planting and aftercare

Many spring bulbs are bought as bare, dry bulbs in fall, before they have come into active growth. It is important to choose firm, healthy bulbs and to plant them as soon as possible. Observe the correct planting depth for each kind of bulb, using free-draining multipurpose potting mix with plenty of crocks in the base of each pot. Keep the pots somewhere sheltered. As the bulbs begin to grow, water more freely.

Once the flowers have faded, either discard the bulbs or allow the foliage to yellow and wither. Bulbs may then be lifted, dried, and replanted in pots, or put in the garden in fall.

*Hyacinthus orientalis* 'Ostara'

*Narcissus* 'Sweetness'

*Iris winogradowii*

*Iris reticulata*

*Iris* 'Katharine Hodgkin'

Alternative plant

*Muscari armeniacum*

# Sizzling tropics

A themed planting of subtropical species in a large pot will look dramatic and exotic until the first frost. Choose a mix of bold foliage and flowers, and try to use a limited palette of "hot colors" to tie in with the terra-cotta pot. Arrange the larger plants toward the center and back. The scheme will look most effective against a neutral background, where the textures and colors of the plants can be more easily appreciated.

## Container basics

**Size** Approx. 24 x 24 in (60 x 60 cm) square terra-cotta pot or a similar-sized round one

**Suits** Subtropical plants with bold flowers and foliage

**Potting mix** Good-quality, multipurpose

**Site** Sheltered, sunny position

## Shopping list

- 1 x *Canna* 'Musifolia'
- 3 x *Begonia fuchsioides*
- 3 x *Crocosmia* x *crocosmiiflora* 'Star of the East'
- 1 x *Pelargonium tomentosum*
- 1 x *Isoplexis canariensis*
- 2 x *Canna* (orange hybrid)

## Planting and aftercare

Arrange the plants carefully in their pots before planting them to see how they will look in their final positions. The scented foliage of the pelargonium is best used spilling over the pot's edge. Place plenty of crocks in the base of the container before pouring in the potting mix. After planting, water well and keep in a greenhouse or cool, light area indoors before placing the pot outside once any danger of frost has passed. Feed the plants regularly during the summer and make sure the soil is kept moist. Deadhead the canna as the blooms fade to encourage further flowers. In fall, before the first frost, bring the pot under cover.

*Canna* 'Musifolia'

*Begonia fuchsioides*

*Crocosmia* x *crocosmiiflora* 'Star of the East'

*Pelargonium tomentosum*

*Isoplexis canariensis*

*Canna* (orange hybrid)

# Color clash

For a dramatic and eye-catching container display, well-considered color clashes can produce the best results, although the careful use of texture and form is even more important in such schemes. Here, yellow variegated foliage contrasts harmoniously with the dark glazed pot, while the rich red mini petunias (*Calibrachoa*) clash. Touches of red in the linear foliage of the grass *Hakonechloa*, though, help to tie the planting together. The gently arching growth of the grass is complemented by the trailing periwinkle (*Vinca*), which mingles well with the petunias that spill over the sides of the pot.

## Container basics

**Size** Approx. 16-in- (40-cm-) diameter glazed pot

**Suits** A mix of bedding plants and garden perennials

**Potting mix** Good-quality, multipurpose

**Site** Sheltered, sunny position

## Shopping list

- 2 x *Hakonechloa macra* 'Aureola'
- 4 x *Calibrachoa* Million Bells Cherry
- 4 x *Calibrachoa* Million Bells Red
- 4 x *Vinca minor* 'Illumination'

## Planting and aftercare

Place a good layer of crocks in the base of the pot for drainage, and add the soil. Position the grass centrally and then plant the *Vinca* and mini petunias around the outside. The petunias are frost-tender, but they will flower for a long season in a sunny position, provided they are kept well fed and watered. In a more shaded spot, the petunias can be replaced by a red busy Lizzie (*Impatiens*) or a bedding begonia. After frost has browned the bedding, surviving plants can be planted out in the garden, or kept in the pot and used again the following year.

*Hakonechloa macra* 'Aureola'

*Calibrachoa* Million Bells Cherry

*Calibrachoa* Million Bells Red

*Vinca minor* 'Illumination'

# Fire and ice

A striking combination of silvery blue foliage and flame red flowers gives this fall-interest container great appeal. The flower power is provided by bedding cyclamen, which often proves surprisingly hardy in a sheltered situation, and should flower well from fall until the first really hard frost. White crocuses could continue the show in spring. Bright silver *Senecio*, tufts of the blue grass *Festuca glauca*, and an upright juniper complete the display. A matching pair of these planted pots would look particularly striking on either side of a doorway.

## Container basics

**Size** Approx. 16-in- (40-cm-) diameter terra-cotta pot

**Suits** Evergreens and winter bedding plants

**Potting mix** Good-quality, multipurpose

**Site** Sheltered spot in semi-shade

## Shopping list

- 1 x *Juniperus chinensis* 'Stricta'
- 2 x *Festuca glauca* 'Elijah Blue'
- 5 x *Senecio cineraria*
- 3 x *Cyclamen hederifolium*

## Planting and aftercare

Place a layer of crocks in the pot and fill three-quarters full with potting mix. Plant the juniper centrally toward the back of the pot and use the grasses to help soften the edges. The cyclamen and *Senecio* can be mingled at the front. (If you are including crocuses, plant them now; they will appear in spring, replacing any cyclamen killed by sustained hard frost.) Top off the pot with potting mix, water well, and place in a sheltered spot in good light. Keep the soil moist but not wet, and deadhead the cyclamen during the winter to prolong the displays. In late spring, the plants can be planted out in the garden, or transferred to a larger container.

*Juniperus chinensis* 'Stricta'

*Senecio cineraria*

*Cyclamen hederifolium*

*Festuca glauca* 'Elijah Blue'

# Winter perfume

This attractive display provides colorful winter cheer and a delicious spicy scent, which comes from the *Sarcococca confusa*, a neat evergreen shrub with little white blooms. While not particularly showy, they scent the air for several weeks. Flower and foliage color is provided by winter pansies (*Viola*), a variegated standard *Euonymus*, and ivy (*Hedera*) to soften the rim of the barrel. You could also add primroses (*Primula vulgaris*), which flower into spring.

## Container basics

**Size** Approx. 24-in- (60-cm-) diameter wooden half-barrel

**Suits** Winter bedding and evergreen shrubs

**Potting mix** Multipurpose with added compost

**Site** Sunny, sheltered spot by a doorway

## Shopping list

- 5 x *Hedera helix* 'Glacier'
- 5 x yellow winter pansies
- 5 x pale yellow winter pansies or 3 x double yellow primroses
- 3 x *Sarcococca confusa*
- 1 x *Euonymus fortunei* Blondy (standard-trained)

## Planting and aftercare

Place crocks at the bottom of the barrel and fill three-quarters full with potting mix. Arrange the plants with the *Euonymus* in the middle, underplanted with the *Sarcococca*, the ivies over the edges of the barrel, and the pansies and primroses in between. Fill in around the plants with potting mix. Water well and keep moist. Position the container where the perfume of the *Sarcococca* will be enjoyed. Remove faded blooms as the season progresses, and any plain green shoots on the *Euonymus*. In summer, replace the bedding with summer flowers, such as busy Lizzies or begonias.

*Hedera helix* 'Glacier'

Yellow winter pansies

Pale yellow winter pansies

*Sarcococca confusa*

*Euonymus fortunei* Blondy

Alternative plant idea

*Primula vulgaris* 'Double Sulphur'

## Design ideas for easy-care gardens

There are a great many reasons why you may want to make your yard easier and less time-consuming to maintain.

Happily, there are numerous strategies and solutions that can be employed without sacrificing aesthetics.

*Pictures clockwise from left*

**Outdoor gallery** The planting of a garden can be quite sparse if each specimen is chosen and sited with care, rather like an arrangement of sculptures. With a simple, uncluttered backdrop, this approach creates an opportunity to really appreciate the form and texture of the plants in your collection. Gravel laid over a weed-suppressing membrane provides a foil for the plants, and to keep the design interesting, aggregates can be enlivened with decorative paving, or cobbles and boulders. In this garden, large rocks anchor the planting, and treated timbers, laid like stepping-stones, direct the eye to a circular mosaic feature with a striking contemporary container providing a focus in the center. Alternatively, you could use a self-contained water feature, such as a bubbling millstone.

**Dining room** Decking brings a roomlike quality and can be used to create a stylish outdoor dining area. This is especially valuable where space indoors is at a premium. To create a visually exciting design that requires very little upkeep, make sure the backdrop and planting around the deck are as simple as possible. A few bold color highlights and nighttime illumination will add designer sparkle.

**Simple division** Larger gardens designed for minimum maintenance are often best divided into a series of compartments. These can be partially screened from one another, or left open to enjoy the sense of space. To give each section its own character, and to add interest, try using contrasting landscape materials—on flat surfaces you can introduce changes in level, such as a raised deck or beds, or a sunken seating area. With a limited planting palette, it is important to be creative with flooring detail, and to include plenty of evergreens, such as the grasses (*Stipa tenuissima*) and sedges (*Carex*) used here.

# Design ideas for easy-care gardens *continued*

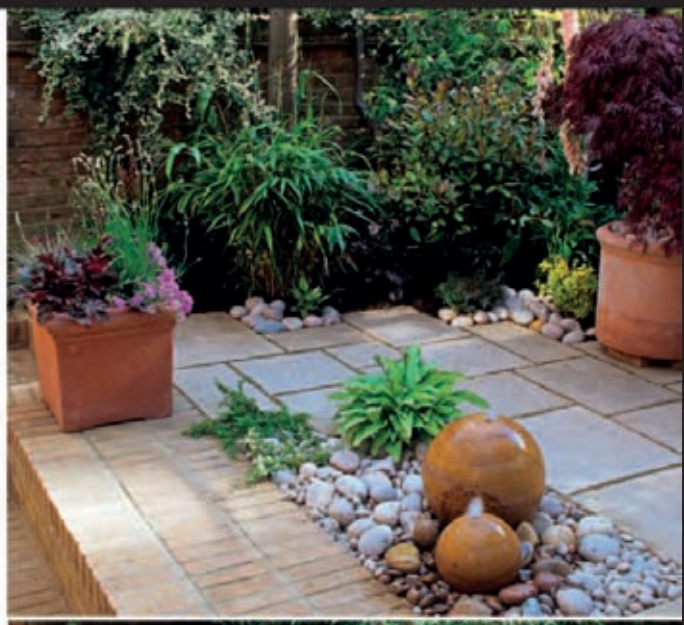
*Pictures clockwise from top left*

**Paved patio** Small, enclosed spaces are perfect for paving—a low-maintenance, relatively weed-free alternative to grass. By planting in raised beds, narrow borders, and pots, you can maintain a range of plants that would satisfy even the most avid gardener. Spend time designing your garden, building in practical requirements as well as incorporating different textures and patterns to create interest. Here, cobbles and a ceramic water feature provide a focus, with hostas and bamboo adding an Asian note.

**Mediterranean garden** This swirling stuccoed wall, painted a dusty terra-cotta, suggests a garden built in a sunny climate. Slender Italian cypress, an old oil jar, and ironwork furniture strengthen the Mediterranean flavor. The wall is the right height to act as impromptu seating and, adding to the ambience, the air is filled with perfume from the white lilies, pink roses, and aromatic herbs.

**Space for children** Although children enjoy playing on lawns, other surfaces are more versatile. Little ones will enjoy a sandbox (covered when not in use), and varying the flooring materials and incorporating changes in level can create opportunities for play. A splinter-free deck suits bare feet and the level surface is ideal for a variety of toys and activities. Choose robust plants, such as the phormium, grasses, and bamboos in this child-friendly garden.

**Raised beds** As well as providing easy-access planting spaces, raised beds are design features in their own right. They also offer casual seating and welcome changes in level in otherwise flat, featureless spaces. This bed, with its curved dry-stone walling effect, provides ideal, sharply-drained conditions for a wide range of hardy alpines.



# Formal design

An ordered or symmetrical garden, with a combination of simple geometric shapes, inspires a feeling of calm. The style is adaptable, and it is easy to create stunning vistas and dramatic focal points.

*Pictures clockwise from top left*

**Creating a focus** The elements of this charming little garden are simple and unfussy, yet because of the strong central axis guiding the eye down the narrow pathway, the effect is quite theatrical. Tall *Verbena bonariensis* are neatly enclosed by clipped dwarf boxwood hedging, which, being evergreen, provides a strong architectural framework, even in the depths of winter. A traditional brick path opens out into a circular paving feature with a large Greek pot at its center, but this could be replaced by a pebble mosaic or an eye-catching piece of sculpture.

**Elegant dining** Although most often associated with grand historic properties, a formal touch, utilizing symmetry, works in a variety of situations and can make a previously ordinary space look stunning. Here, French windows open out onto a raised deck used for dining. Elevated views of the garden are framed by tall, stylish containers filled with lavender, and a grapevine-covered arbor. The formality continues with matching steps, clipped boxwood edging, and twin potted marguerites.

**Contemporary twist** There's no reason why you can't take elements of Renaissance gardens and use them to add style to a contemporary space. Here, tall perennials (*Miscanthus* and *Rudbeckia*) are contained by low evergreen hedging—just like a modern-day parterre—and clipped topiary in matching terra-cotta pots makes a stylish statement. A rill or narrow canal set into the deck would also work well.

**Mirror image** This study in symmetry and minimalism has created a garden that is extremely easy to maintain. Simply planted, the design succeeds by clever stage-setting. The onlooker's eye is drawn to the water curtain sculpture by a line of cube-shaped box topiaries running along the central axis. Meanwhile, the two formal white containers, matching raised beds planted with bamboo, and the arching tree branches frame the view perfectly. Keep the surfaces immaculate to avoid visual distractions.

## Contemporary creations

Modern minimalism has much to offer busy garden owners. Simple layouts, easily maintained hard landscaping, and color and interest that don't rely solely on planting are useful elements often exploited by contemporary designers.

*Pictures clockwise from far left*

**Color impact** Use bold shades, like purple or red, to enhance contemporary designs and create exciting backdrops. Here, architectural foliage plants, including phormium and eucalyptus, are all the more striking against the painted fence. A stuccoed wall could also act as a modern minimalist canvas, if painted with masonry paint.

**Sculptural focus** The gleaming white spiral of this art installation stands out dramatically against the dark uncluttered backdrop and restrained planting plan. Alternative sculptural elements, such as a large container or fountain, could be used to create a focal point strong enough to carry the simple design.

**Restrained planting** While gardens often rely on colorful flowers and foliage for interest, you can still create an attractive outdoor space using a limited planting palette. This ground plan is well defined, and strengthened by innovative flooring and dividing walls. Only a few of the rectangular compartments contain plants—many are filled with water and bridged by decking walkways.

**Novel materials** You can achieve contemporary effects with high-tech materials. Consider acrylic plastic panels, or polished and galvanized metal sheeting for facing walls and edging beds, and metal grids for flooring. Here, corrugated metal contains a grass-filled border.

**Simple composition** Taking inspiration from Zen gardens, this simple but effective layout, with a background of white stone chips and black trellises, features a single phormium surrounded by carefully selected rocks and a black glazed sphere.

# Havens for wildlife

Low-maintenance gardens can be surprisingly wildlife-friendly. Many easy-care plants attract bees and butterflies, and shrubs and trees with ornamental fruits offer a feast for birds.

*Pictures clockwise from top left*

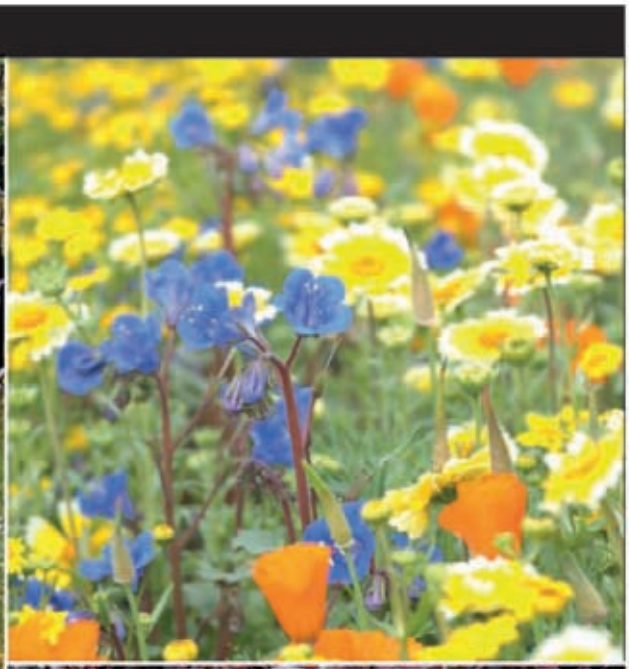
**Watering hole** Providing a safe vantage point to drink and bathe, a birdbath can become a hive of activity for birds; site conveniently, as you'll need to top it off regularly. To avoid problems with cats, plant around the base with low ground cover. Here, blue fescues (*Festuca*), houseleeks (*Sempervivum*), and sedums are used. A shallow-sided pebble pool would also attract amphibians and dragonflies.

**Carefree meadow** One way to reduce the need for regular mowing in a large garden, while increasing wildlife potential, is to convert sections of formal lawn into wildflower meadows. On poor, sandy soil, you can establish a meadow using wildflower plugs and bulbs suitable for naturalizing. More reliable results are achieved by removing sod with a sod-cutting machine and then re-sowing with a perennial wildflower mix.

**Insect attractors** Beneficial hoverflies seek out single-flowered annuals, such as *Eschscholzia* and *Limnanthes*, and bees love blue flowers like this California bluebell (*Phacelia campanularia*). *Verbena bonariensis* and *Buddleja davidii* are magnets for bees and butterflies. For the first insects of the season, plant sunny gravel or raised beds with spring alpines—alyssum, arabis, aubrieta, heathers, grape hyacinth (*Muscari*), and crocus.

**Bird cover** Large evergreen and deciduous shrubs, dense hedges, and trees are vital for birds. They not only need safe nesting and nighttime roosting sites, but also places to shelter during bad weather and to escape airborne predators. Without cover nearby, birds are nervous about entering a garden, even one with feeders.

**Berry banquet** Provide a wide range of fruiting and berrying plants, with some ripening in late summer and others ready for harvest well into winter. This long-lasting buffet will cater to local birds as well as visiting migrants. Low ground-cover plants such as *Cotoneaster salicifolius* 'Gnom' (*illustrated*), wall shrubs like pyracantha, roses with large colorful hips, and small ornamental trees, such as rowans (*Sorbus*) and crab apples (*Malus*), are ideal.



# Courtyard gardens

Textures and colors are viewed close up in these intimate spaces, so choose materials and plants for maximum effect. Also include some shade and water, as well as lighting for evenings outside.

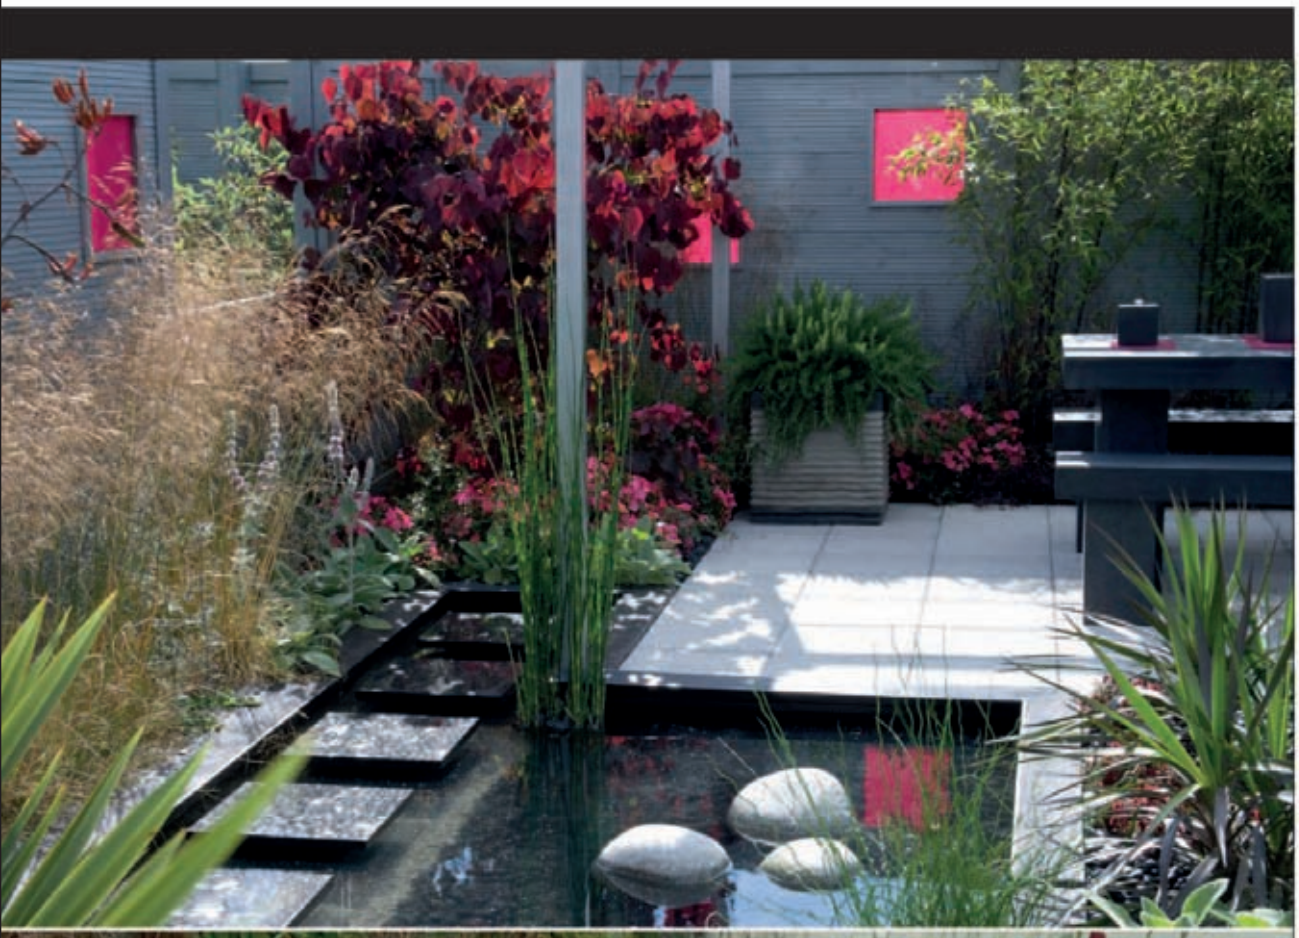
*Pictures clockwise from top left*

**Big, bold pots** Some outdoor spaces are completely paved, but you can grow almost any plant in a container—provided it is big enough—including small trees, elegant bamboos and grasses, a wide range of shrubs and climbers, as well as perennials, bulbs, and ferns. This pot contains *Nandina domestica*, purple cordyline, heuchera, and trailing ivy. Evergreens help the garden look good all year, and courtyards often have a sheltered microclimate, allowing less hardy species to be grown. Install automatic irrigation to make light work of watering.

**Tranquil oasis** This striking, contemporary walled garden has a Moorish feel. The lush planting, inspired by a rich purple and cerise color palette, features a glowing *Cercis canadensis* 'Forest Pansy' in the corner, and a large formal pool with "floating" stepping-stones. The arbor-covered, paved terrace juts out over the surface, taking you right to the water's edge.

**Hot property** Courtyards can feel gloomy if surrounded by high walls, but you can lift the atmosphere and create more light by applying color (on taller walls, just paint to a line above the ground-floor windows). Here, a vibrant orange has been used on a curved wall, contrasting with beds of Mediterranean herbs, perennials, and grasses. Where shade is a problem, whitewashed walls may appear to be the answer, but these need frequent touching up and white can seem harsh in a cool climate; instead, try light pink, pale green, watery blue, or pearly gray. Also consider wall-mounted mirrors or reflective metal panels, murals and *trompe l'oeil* (illusory 3-D effects) or, for a historic look, decorative trellis panels.

**Garden café** Courtyards can be transformed into an extra room for your house, and an *al fresco* dining room or outdoor kitchen can be used in fine weather at any time of year. Raise or sink the dining area to give it definition, and construct screens with giant pots or raised beds filled with architectural evergreens, like the cordyline and clipped boxwood balls in this stylish garden.



# New-wave planting

This impressionistic style of gardening, sometimes known as prairie planting, uses harmonious combinations of herbaceous perennials and ornamental grasses to create naturalistic and long-lasting displays.

*Pictures clockwise from top left*

**Planting philosophy** Choose easy-care perennials that don't need deadheading, staking, or frequent division. Plants that have everlasting flowers or sculptural seedheads in fall and winter are particularly useful; most grasses, even deciduous types, retain foliage and diaphanous seedheads through winter. For the prairie look, plant swaths of single cultivars and punctuate with isolated clusters. Soften the effect of heavier flower and foliage forms by using airy flower stems and billowing grasses, and vary the height of plants to create interesting undulations. Here, crimson astrantia rise above a ribbon of erigeron interspersed by tussocks of *Stipa tenuissima*.

**Stylized nature** Planted *en masse*, color-restricted displays of flowering perennials and grasses produce a stylized, contemporary version of a meadow. Here, raised beds lift the planting to create a feeling of enclosure around this outdoor dining area. An elegant mixture of tall miscanthus grasses and *Verbena bonariensis* opens up to reveal blocks of lavender on the opposite side.

**Lingering effects** From midsummer onward, *Rudbeckia fulgida*, as well as plants like the heleniums and achilleas seen growing here, put on a long-lasting show. Interspersed with hardy grasses—such as calamagrostis, miscanthus, panicum and stipa—they knit together seamlessly, covering the ground and preventing weed growth. Many of the grasses also flower in late summer, adding to the display, and the foliage fades to biscuit or develops red and purple hues as fall approaches. It is only necessary to cut back hard when growth begins again in spring.

**Grassy retreat** The planting in this gravel garden is relaxed and informal—the seating area is completely cocooned by billowing grasses, and narrow pathways wind lazily through the subtle planting. Although there are few colored blooms, this garden will change throughout the year and will look magical with a dusting of frost.

# Benefits of a low-maintenance garden

With adjustments to your existing yard, or strategic planning when building from scratch, you can enjoy a beautiful garden even if you have little time or energy to care for it. Most high-maintenance plants and plans have low-maintenance alternatives, and many routine jobs can be omitted altogether.

## Who needs a low-maintenance garden?

We simply do not have as much time as we used to, and yet the garden is increasingly seen as a sanctuary and an antidote to modern living. Whether you are pursuing a career, working odd shifts, spending hours commuting, or raising a young family, you will need to find a way to manage your garden more easily.

New gardeners may lack confidence in their abilities and want to start simply, and some homeowners are not particularly interested in the practical side of gardening, yet still appreciate and desire an attractive outdoor space. Older gardeners may find they no longer have the physical strength and energy to cultivate in the way they used to or, adopting a more carefree lifestyle, might be too busy traveling to garden regularly. And if you are a landlord with rental properties, you may only be able to visit them a few times a year.

Creative design and planting will ensure that ultra-easy-care gardens like this urban yard are attractive, practical, and never boring.

With easy-care gardening strategies in place, you can cut down on regular or seasonal chores like raking leaves and lawn maintenance.

## How much time do you have?

When designing your yard, first think about how frequently you will have time to maintain it.

**Weekends** If you have a few hours on the weekend, you may only have time to mow the lawn, do a little deadheading and tidying up, and perhaps do some hand-weeding, hoeing, or hedge-trimming. Drought-tolerant shrubs and flowers in pots will survive with weekly waterings.

**Once a month** Lawns are not a good idea if you can only tackle gardening tasks once a month. Instead, replace them with paving, decking, or gravel. Reduce deadheading and pruning with a selection of easy-care plants, and install an automatic watering system.

**A few times a year** Gardening only once in a while restricts your options, so choose a combination of low-maintenance plants and hard landscaping. You can then limit jobs to tidying up borders, cutting back old growth on perennials in late winter, and occasionally pruning overgrown trees and shrubs.

## Time-saving tips

**Watering** Select drought-tolerant specimens, and plant in fall or spring to cut down the need to water while the roots are establishing. Set up pots with automatic irrigation.

**Fertilizing** Mulch with manure in late winter to keep the soil fertile. Once or twice a year, fertilize flowering plants, including those in containers, using a slow-release fertilizer.

**Deadheading** Choose plants with ornamental seedheads and avoid any that need deadheading to keep them blooming. Tidy up ground-cover perennials and lavenders with shears.

**Weeding** Cover the ground with a weed-suppressing fabric camouflaged with gravel. Spray weeds with systemic weedkiller to kill the roots. Avoid soil disturbance and self-seeding plants.

**Mowing** Choose an easy-care grass seed mix. Reduce the lawn size and buy an efficient mower. Install a brick mowing strip next to borders and walls to eliminate edging.

**Pruning** Choose evergreens, as they rarely need pruning, and plants that only need one trim per year, such as *Buddleja davidii*. Avoid overly vigorous shrubs and allow plants room to grow.

# Low- and high-maintenance ingredients

Choose the plants and materials in your garden carefully to minimize the workload.

## Easy-care gardens

Paved or decked surfaces are easy to keep clean and weed-free, and surrounding your plants with hard landscaping, or growing them in raised beds, keeps them within bounds; you can also carry out most jobs in nearly any weather. Although there is an excellent selection of low-maintenance flowering shrubs and perennials, choosing specimens for their architectural qualities, foliage color, and texture, rather than for their blooms, will ensure that the planting is interesting year-round.

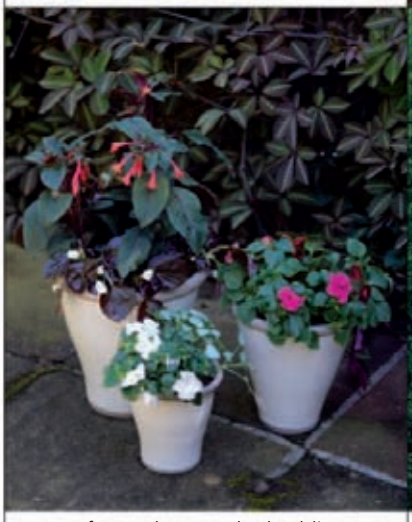
**Hardy bulbs** Dwarf and low-growing hardy bulbs, like crocus, scillas, and small daffodils, offer a maintenance-free spring show. For summer, plant alliums and low-growing lilies that do not need staking. Dying down gracefully, these bulbs are left in the ground to come up year after year.

**Drought-busters** Plants like these houseleeks do not need watering at all. If you live in a dry region, or the garden has a hot, sunny exposure and free-draining soil, focus on drought-tolerant plants, such as succulents or silver-leaved varieties. Avoid pots or consider installing automatic irrigation.

**Plant-free features** Bringing color into the garden with painted walls or trellises reduces the need for bright bedding displays. Decorative paving elements, such as pebble mosaics, add textural interest, while sculpture and stylish outdoor furniture provide maintenance-free highlights.

## Labor-intensive gardens

Manicured lawns require a lot of upkeep: mowing and edging, weeding and feeding, moss-killing, scarifying to remove dead material, aerating to improve drainage, and sweeping up leaves in fall. Of course, a roughly maintained family lawn, or one where clover and other attractive "weeds" are allowed to grow, needs much less attention. Traditional borders full of blooms, and backed by flower-festooned walls and fences, look spectacular in summer, but it is difficult to keep on top of deadheading, staking, weeding, and watering, not to mention tying climbers and wall shrubs onto their supports. Self-seeding can also become a time-consuming problem.



**Pots** If you plant tender bedding plants, annual flowers, and bulbs in containers, you are committing yourself to time-consuming tidying up as well as daily watering in hot weather, and regular fertilizing to keep plants healthy. At the end of each season, displays have to be replanted.

**Fast-growing hedge** One of the most challenging tasks is staying on top of quick-growing plants, like privet and tall conifers. Several cuts a year are required to maintain a neat profile and control height and spread, and removing the clippings can also be laborious.

**Tender plants** A recent trend in patio gardening has seen an increase in the use of exotics, such as bananas, tree ferns, cannas, and agaves. These plants are too large and expensive to discard at the end of summer, but need to be fully protected from frost *in situ* or in a greenhouse.

# Assessing your site

Look critically at your yard before carrying out any major changes. Weigh up the pros and cons of features before removing them, and remember that mature, established plants may need less maintenance than new ones.

**Which way does your yard face?** Work out where the sun rises (east) and sets (west). Eastern exposures are sunny in the morning—winter and spring-flowering shrubs are vulnerable to frost here. West-facing walls and fences have sun in the afternoon and evening—ideal for relaxing after work. Areas in sun for much of the day are south-facing, and shady, cool spots opposite have a northern exposure.

## What do you need?

Make a list of the various activities and areas planned for your yard, including places for growing plants, supporting wildlife, relaxing, cooking, and dining *al fresco*. Bear in mind factors like sun and shade, drainage, shelter from wind, and proximity to water and electrical outlets. Don't forget practicalities like easy access to garbage cans or recycling bins and compost piles, as well as storage space for garden tools and furniture.

Guinea pigs and rabbits like to graze and run on grass; lawns also benefit songbirds.

Make children's gardens versatile, and easy to adapt when they tire of play equipment.

Areas for outdoor entertaining might include a grill, a sunken fire pit, or a gazebo.

## Understanding climate

You can live in an area that suffers from early and late frosts or that's battered by winds, while enjoying milder conditions in your garden. South- and west-facing yards are suntraps; walls and paving absorb daytime heat and radiate it back at night, keeping surrounding areas frost-free. Trees and hedges act as buffers against wind but, conversely, buildings can cause damaging turbulence. Such local variations are known as microclimates.

As sunny walls radiate heat, tender plants like this ceanothus can thrive in frosty regions.

Hedges and shrub borders slow the wind and provide shelter for plants and people.

Cold air pools at the bottom of slopes, and plants here are more vulnerable to frost.

# Boundaries and garden dividers

The style and fabric of the elements you choose to enclose or separate parts of your yard have a major impact on the overall effect of the garden. Boundary materials frequently act as a foil, but can also make a bold statement.

**Wooden fence** Choose the highest-quality fencing that you can afford for long-lasting results. Pressure-treated posts are easier to replace and last longer if placed into metal sockets rather than directly into concrete.

**Trellis** A decorative screening material with panels in various styles, a trellis may also include shaped pieces for special features. Letting in more light but offering less privacy than solid paneling, it is best for internal divisions.

**Willow or hazel hurdles** These hand-woven panels are perfect for cottage-style gardens. For a contemporary look, attach to aluminum posts or a solid lumber frame. Panels last for about eight years.

**Stucco wall** Cinder-block walls are quicker and cheaper to build than brick and, when stuccoed, can be painted in a range of colors to create a smart and stylish finish. Stucco is often used for contemporary designs.

**Brick wall** Garden walls are decorative and practical, and frostproof bricks are available in a range of styles to match adjacent buildings. Antique or reclaimed bricks create the illusion of age and are ideal for historic gardens.

# Green dividers

Fences and walls provide opportunities to grow a wide variety of climbers and wall shrubs, and the plants help to camouflage boundary imperfections. Also, living screens of tall ornamental grasses, bamboos, shrubs, and trees offer exciting alternatives to formal hedging.

**Bamboo screen** Some bamboos make beautiful evergreen screens, which suit both Asian-style and contemporary yards. Non-invasive, clump-forming cultivars of *Phyllostachys* and *Fargesia* are ideal, their upright canes often developing attractive tints and banding. Plant a row in moisture-retentive ground, allowing them room to spread sideways. To control the width of the screen, remove unwanted bamboo shoots at ground level in late spring. Periodically thin out some mature canes, and remove leafy growth from the lower half of the screen.

**Climbers** There are only a few climbers that are self-clinging and do not require wires or trellis. These include *Hydrangea anomala* subsp. *petiolaris* (*above*) and ivy. Be sure to choose the right plant for the site and soil type—some prefer cool shade, while others bloom best on a sunny wall. Also consider the plant's ultimate height and vigor, to avoid problems in the future.

**Yew hedge** When clipped formally, this dark evergreen forms a dense wall or plain backdrop for borders. Relatively slow-growing, it can eventually be trained into arches and other pieces of green architecture. Yew is long-lived and regenerates from old wood if pruned hard. Although shade-tolerant, hedges are best cut wide at the base and narrow at the top, so that light falls evenly on the foliage.

**Tree and shrub divide** Ideal for protecting windswept gardens, a boundary of trees and shrubs makes a particularly effective shelterbelt. Mix different shapes, textures, and colors, including flowering and berrying types, for maximum interest, and prune to control size.

**Living willow screen** In heavy clay soil, willow stems pushed into the ground will root easily. Setting these hardwood cuttings at an angle forms the beginning of a diamond lattice. Simply hook the willow stems under and over one another to the desired height, and then weave the excess at right angles to secure the upper edge of the screen. Trim the stems as necessary.

**Fedge** This is a cross between a fence and a hedge, and is an ingenious way to camouflage ugly chain-link fencing. It is best to use a plain green ivy for rapid cover and to produce a slim, dense, hedgelike structure. Plant pots of young, vigorous ivies at the base of the screen, and weave the shoots in and out as they grow. Once the fence is covered, trim the ivy using hand shears.

# Selecting landscape materials

The natural or synthetic products you choose, and the patterns and designs you employ, make a big difference to the overall look of the garden. Other considerations include the cost of materials, ease of laying or installation, and long-term durability.

**Granite pavers** These hard-wearing cubes of granite are ideal for driveways and areas in heavy use, and can be arranged to make very attractive circular, curving, or interlocking paving patterns as well as the straightforward grid design illustrated. Made of natural stone, these paving blocks suit historic properties and country residences, but they can also be used in a variety of situations to add textural interest to areas paved with slabs. Granite pavers are expensive but concrete substitutes are available.

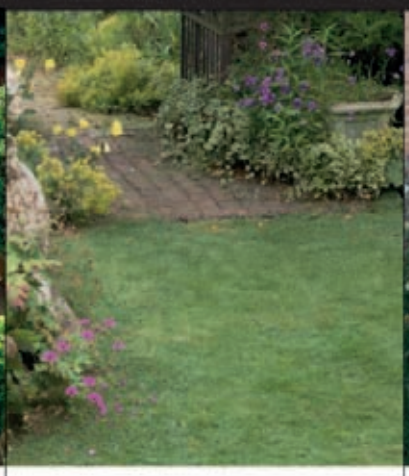
**Using contractors** When hiring someone to carry out hard landscaping work, be prepared to show them a scale drawing or at least mark out the areas to be paved or decked to avoid confusion. Get a number of quotes and, especially if the contractor hasn't been personally recommended, ask to see examples of their work so that you can do your own quality check. After considering your ideas, contractors may help you select suitable materials and provide paving samples; also discuss clearing and preparing the ground, waste removal, drainage requirements, electrical wiring, and paving patterns and designs. Once you are happy with a quote, draw up a formal agreement for the contractor to sign, stating exactly what you expect them to do for the price, with start and end dates.

**Natural stone** Ethically sourced sandstone, limestone, and granite paving reveals subtle colors when wet and does not chip or fade, but it tends to be thicker, heavier, and less uniform, and is more expensive than concrete reproductions. Consider hiring an experienced paving contractor.

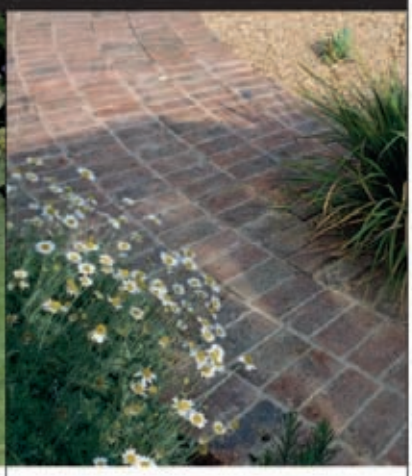
**Concrete paving** There is a wide range of concrete paving available, from plain, contemporary designs to textured stone reproductions and modular paving sets. Quality varies, and some styles are thicker and more hardwearing with better resistance to chipping or fading in sunlight.

**Woodstone** A convincing substitute for wooden landscape timbers, the concrete is imprinted with the texture of weathered, reclaimed wood and suits country or cottage garden situations. It can also be used for steps, stepping stones in gravel, and to construct low raised flower beds.

**Wooden decking** Decking is warm underfoot and dries rapidly after rain. Do not use in shady areas as it quickly develops slippery algae. Off-the-shelf kits are available from do-it-yourself stores, but hire a specialist for larger, more complex areas. Western red cedar is naturally rot-resistant.



**Sod** New gardens are often laid with sod prior to implementing a design. A well-maintained lawn makes an attractive foil for borders and contrasts well with hard landscaping. Lawns are important for many birds and provide a safe play surface for children. Install a mowing edge.



**Bricks** Frostproof bricks, engineering bricks, and pavers can be laid in a wide variety of patterns, such as curving shapes and circular designs; they also add texture to areas paved with slabs. Bricks come in different shades and styles, including antique effects that suit older properties.

**Cobbles** Pebbles and cobbles of different colors and grades can be used with other materials, such as slate shards and tile fragments, to create paving mosaics like the circular feature above. Simple designs are not difficult to make, as the pebbles are bedded into a dry mortar.

**Gravel** This versatile and inexpensive material comes in many different grades and colors, allowing it to blend with other landscape materials. Laid over a permeable membrane, it's an easy way to create pathways and patios. Contain gravel to separate it from soil using slightly raised edgings.

**Decorative aggregates** Slate chips (*above*) are one of several stone aggregates now available for garden landscapes. More dramatic or contemporary effects can be created with colored stone chips and glass chips. Lay as for gravel, over a permeable membrane.

# Designing with different materials

Hard surfaces act as a framework around which plants can grow and mature. The chosen material, and the style in which it is laid, can enhance the design of your outdoor space.

**Decking jetty** This substantial wooden platform hangs over the pool below, allowing close access to the water. The clean lines and restrained planting combine to create an open expanse of warm wood and tranquil water.

**Basketweave bricks** This garden is paved in a traditional design that suits older properties and has cottage-garden appeal. The weathered terra-cotta coloring and intricately textured surface of the bricks give an aged quality.

**Sleek slabs** Smooth, simple concrete pavers laid in a uniform row or geometric grid create a contemporary feel. This minimalist style of paving helps to emphasize the planting as well as architectural and design features.

**Vintage stone** Reclaimed stone from architectural salvage companies gives a garden a feeling of permanence. The worn and weathered surface of the stone adds character, perfect for this formal pool terrace edged in boxwood.

**Zen gravel garden** Gravel is used here to emulate a dry Zen garden or *karesansui.* The rugged boulders and simple evergreen plantings represent islands in a sea or lake, reflecting traditional Japanese designs.

# Spring mix

This woodland carpet could be recreated under the dappled shade of deciduous trees or large shrubs. The planting reaches its peak in early spring when the snowdrops open and the bronze-pink fronds of the maidenhair fern (*Adiantum*) unfurl. The marbled arum foliage makes a lovely foil for various forms of hellebore that flower through winter; select these in bloom, as catalog descriptions can be misleading. The colored petals are long-lasting and the nodding flowers of *H. orientalis* subsp. *guttatus* have speckled throats.

## Border basics

**Size** 5 x 5 ft (1.5 x 1.5 m)
**Suits** Shade-loving woodland plants that flower in late winter or early spring
**Soil** Moist, with a deep organic mulch
**Site** Under trees or north-facing border

## Shopping list

- 7 x *Adiantum venustum*
- 9 x *Arum italicum* subsp. *italicum* 'Marmoratum'
- 5 x *Helleborus* x *hybridus* cultivar
- 5 x *Helleborus orientalis* subsp. *guttatus*
- 50–100 x *Galanthus nivalis*

## Planting and aftercare

Work in plenty of well-rotted manure, garden compost, or leafmold to improve clay soil or make sandy or free-draining ground more moisture-retentive. Plant the border in fall or in mild spells during winter and early spring. Pot-grown snowdrops, or those lifted and replanted in clumps just after flowering, often establish better than dry bulbs planted in early fall. Mulch with chipped bark or cocoa shells to retain moisture and suppress weeds. Remove old leaves from the hellebores when the flowers start to open so that they don't mar the display. Also snip off dead or damaged leaves from the maidenhair fern when the new fronds unfurl.

*Arum italicum* subsp. *italicum* 'Marmoratum' ❄❄❄ ◑ ☀

*Helleborus orientalis* subsp. *guttatus* ❄❄❄ ◑ ☀

*Galanthus nivalis* ❄❄❄ ◊ ◑ ☀

*Helleborus* x *hybridus* cultivar ❄❄❄ ◑ ☀

*Adiantum venustum* ❄❄❄ ◑ ☀

# Sparkling summer bed

This silver and pink color scheme is perfect for a sunny hot spot. Dotted through the planting, metallic-leaved astelia, commonly called silver spear, adds a distinctly Mediterranean feel. The compact form of the evergreen *Artemisia schmidtiana* appears like a shimmering river running through the border, with blue-leaved fescues on one side and pink-flowered thrift or sea pink on the other. The thrift (*Armeria*) blooms from late spring into early summer from wiry green tussocks. At the rear, the cut-leaved artemisia adds height and texture.

## Border basics

**Size** 6 x 5 ft (1.8 x 1.5 m)
**Suits** Drought-tolerant grasses, alpines, and perennials
**Soil** Sharply drained
**Site** Hot, sunny, and sheltered

## Shopping list

- 3 x *Astelia chathamica*
- 3 x *Artemisia ludoviciana* 'Valerie Finnis'
- 7 x *Artemisia schmidtiana* 'Nana'
- 7 x *Festuca glauca* 'Blauglut'
- 9 x *Armeria maritima* 'Splendens'

## Planting and aftercare

Prepare heavier ground by digging in plenty of grit to improve drainage. This layout is best planted in late spring when the weather has become warmer and drier. Plants like the slightly tender astelia will have a chance to establish before winter and the grasses and silvery artemisias should be in active growth. To maintain the display, cut back dead heads on the thrift and, at the end of the season, the dead stems of the broad-leaved artemisia. Cover the astelia with floating row cover if a cold snap is forecast, and mulch with bark to protect the roots. In spring, tidy up the grasses by combing the dead leaves out of the tussocks with your fingers. Lightly trim the evergreen artemisia with shears.

*Astelia chathamica*

❄❄❄ 💧 ☼

*Armeria maritima* 'Splendens'
❄❄❄ 💧 ☼

# Elegant fall border

This sparkling arrangement starts blooming in midsummer. First in flower is the pearly everlasting (*Anaphalis*) with clusters of papery ball-shaped heads, which remain attractive for many weeks, over gray-green felted leaves. Mingled in, the vibrant aster 'Veilchenkönigin' is a Michaelmas daisy with compact growth and good disease resistance. At the back, Russian sage (*Perovskia*) makes a delicate but long-lasting foil (try globe thistle, *Echinops*, as an alternative) and clumps of stipa add structure and movement.

## Border basics

**Size** 6 x 4 ft (1.8 x 1.4 m)
**Suits** Late summer- and fall-flowering perennials and grasses
**Soil** Well-drained, neutral to alkaline
**Site** Open, full sun

## Shopping list

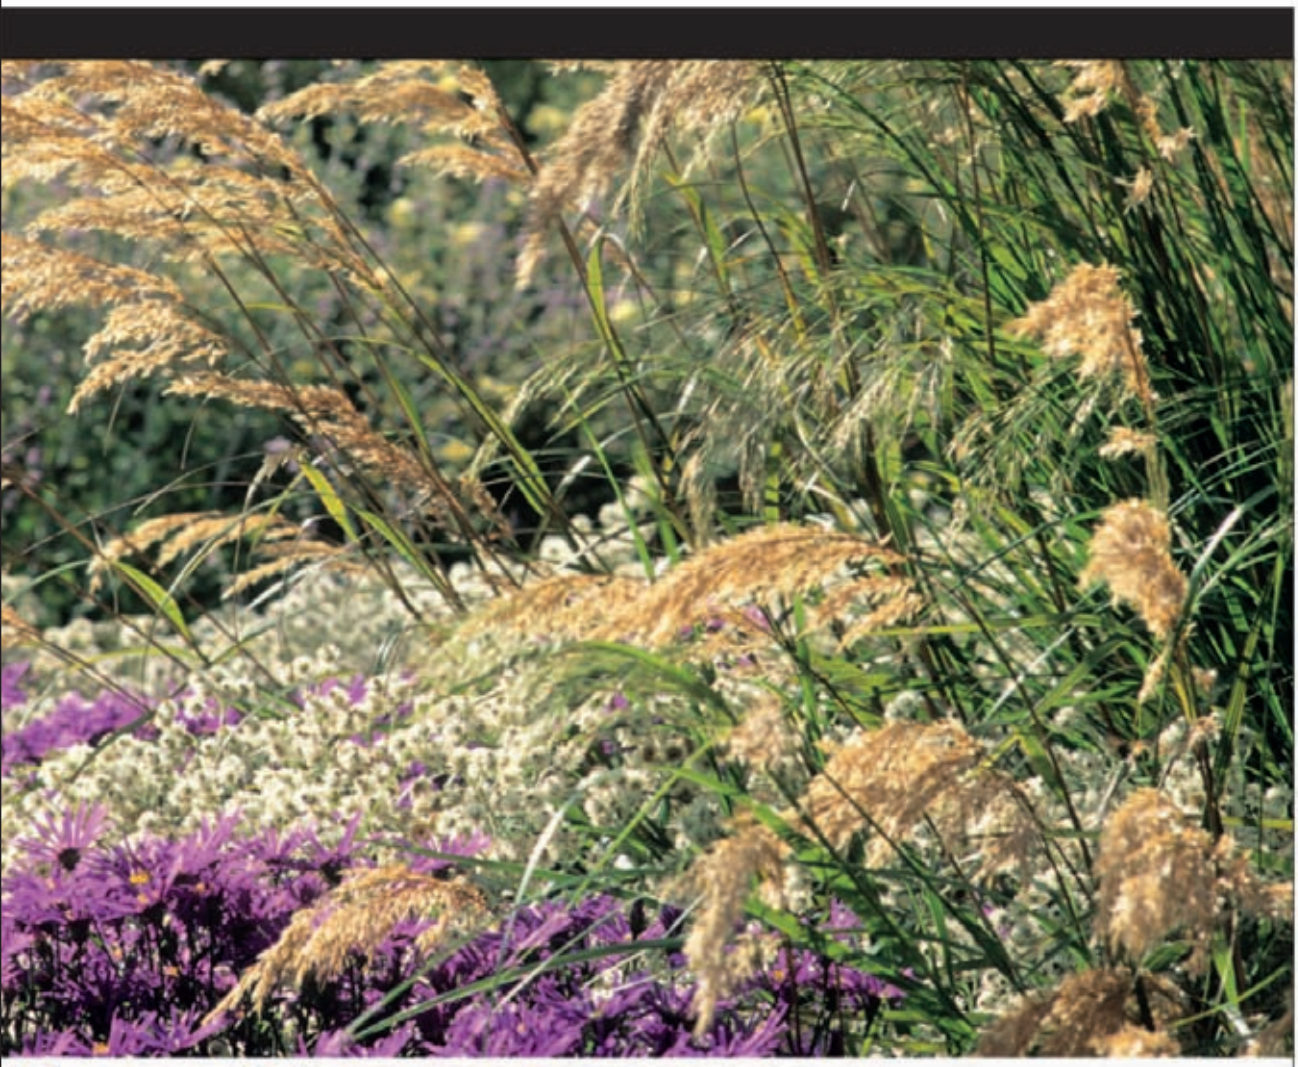
- 3 x *Stipa calamagrostis*
- 5 x *Aster amellus* 'Veilchenkönigin' syn. Violet Queen
- 5 x *Perovskia atriplicifolia* 'Blue Spire' or 5 x *Echinops ritro*
- 7 x *Anaphalis triplinervis*

## Planting and aftercare

The plants in this plan enjoy fertile, well-drained soil, so remedy any drainage problems before planting in spring, and dig in organic matter if the soil is poor and dry. After soaking the pots, lay the plants out in long overlapping drifts. This arrangement suits relatively narrow borders because it creates the illusion of depth. Intermingle the asters and pearly everlasting where the two drifts meet to give a more naturalistic feel. Mulch to retain moisture, keep down weeds, and help plants establish through the summer months. In midwinter, cut down old flower stems of foreground plantings if they look untidy, but delay cutting back the grass and Russian sage until spring.

*Stipa calamagrostis*
❄❄❄ 💧 ☼

*Aster amellus* 'Veilchenkönigin'
❄❄❄ 💧 ☼



*Perovskia atriplicifolia* 'Blue Spire'

*Anaphalis triplinervis*

Alternative plant idea

*Echinops ritro*

# Winter color

The flame-colored willow (*Salix*) sets this sunny border alight. It thrives in heavy soil, including waterlogged clay. Hard pruning in spring helps control its vigor, but in a small garden, consider using the dogwood *Cornus sanguinea* 'Midwinter Fire' instead. The ghostly white-stemmed rubus has dainty divided leaves in summer—a subtle contrast with the diaphanous stipa. In heavier soil, consider replacing this grass with the coppery pheasant's tail (*Anemanthele lessoniana*). In winter, the tawny red sedum flowers dry out, forming stiff, long-lasting maroon heads.

## Border basics

**Size** 6 x 6 ft (1.8 x 1.8 m)
**Suits** Deciduous shrubs, grasses, and late-flowering perennials
**Soil** Fertile, well-drained, not too dry
**Site** Full sun

## Shopping list

- 1 x *Salix alba* var. *vitellina* 'Britzensis'
- 1 x *Rubus thibetanus*
- 7 x *Sedum* 'Herbstfreude'
- 9–11 x *Stipa tenuissima*

## Planting and aftercare

For best results, plant in spring to allow plants to establish before putting on a show through the winter. Cut the white-stemmed rubus and willow back hard the following spring to encourage plenty of new stems, which color up better than the old. Also cut back the grass foliage as you see new growth appearing, and clear away old sedum stems. Every three years, lift and split the sedum clumps in spring to keep them strong and stop them from collapsing during late summer. Apply a granular, slow-release fertilizer annually in spring and/or well-rotted manure at pruning time. Consider adding tall *Verbena bonariensis* for extra color in the "quiet" summer phase of this display.

*Salix alba* var. *vitellina* 'Britzensis'

*Rubus thibetanus*

*Sedum* 'Herbstfreude'

*Stipa tenuissima*

# Cool foliage collection

In spring, the lungwort (*Pulmonaria*) puts on a display of white blooms, and the silver-spotted leaves that follow are just as attractive. The cream-variegated elder (*Sambucus*) brightens this shady spot, and clumps of dwarf boxwood (*Buxus*), along with the cherry-red stems of variegated dogwood (*Cornus*), maintain structure in winter. Tall flag iris makes a bold vertical statement and, though normally grown in water, its vigor is controlled in drier soil. Silver curry plants (*Helichrysum*) thrive in a patch of sunlight.

## Border basics

**Size** 6 x 12 ft (1.8 x 4 m)

**Suits** Shade-tolerant shrubs and perennials grown for foliage contrast

**Soil** Fertile, moisture-retentive

**Site** Cool, lightly shaded

## Shopping list

- 1 x *Cornus alba* 'Elegantissima'
- 1 x *Sambucus nigra* 'Marginata'
- 3 x *Helichrysum italicum*
- 3 x *Iris pseudacorus* var. *bastardii*
- 7 x *Pulmonaria saccharata* 'Sissinghurst White'
- 3 x *Buxus sempervirens* 'Suffruticosa'

## Planting and aftercare

Most plants here would thrive in clay-rich soil. Improve dry soil by working in plenty of well-rotted manure. The curry plant requires sharply drained ground, so dig in plenty of grit before planting, or swap for pearly everlasting (*Anaphalis triplinervis*) as this tolerates clay and shade. Siberian iris (*Iris sibirica*) could also replace the flag iris. Mulch with bark after planting. Clip the boxwood to shape in early summer. In early spring, prune the elder back to a low framework and, once established, remove a third of the oldest stems of the dogwood. Prune the curry plant in spring to keep it bushy, and if mildew attacks the pulmonaria, cut back, fertilize, and water to aid regrowth.

*Cornus alba* 'Elegantissima'

*Sambucus nigra* 'Marginata'

*Helichrysum italicum*

*Iris pseudacorus* var. *bastardii*

*Pulmonaria saccharata* 'Sissinghurst White'

*Buxus sempervirens* 'Suffruticosa'

# Architectural designs

All these plants have such a sculptural profile that the overall effect is very dramatic. The yellow-stemmed bamboo (*Phyllostachys*) makes an effective screen and, building a subtropical theme, two bold variegated yuccas dominate the foreground. Giant feather grass (*Stipa gigantea*) carries shimmering seedheads well into fall, its vertical form contrasting with the spreading tussocks of the New Zealand sedge (*Carex comans*). This bronze evergreen's color and form work beautifully with the broad, thick, textured foliage of the blue-leaved hosta and spiky black ophiopogon.

## Border basics

**Size** 8 x 8 ft (2.5 x 2.5 m)
**Suits** Sculptural evergreens, bamboos, and grasslike plants
**Soil** Well-drained to moisture-retentive
**Site** Sunny

## Shopping list

- 1 x *Stipa gigantea*
- 1 x *Phyllostachys aureosulcata* f. *aureocaulis*
- 2 x *Yucca filamentosa* 'Bright Edge'
- 3 x *Hosta sieboldiana* var. *elegans*
- 5 x *Ophiopogon planiscapus* 'Nigrescens'
- 3 x *Carex comans* bronze-leaved

## Planting and aftercare

Prepare individual planting holes. The stipa, yucca, and ophiopogon thrive in sharply drained soil, so in heavier soil, work in plenty of grit. The sedges, hostas, and bamboo, meanwhile, enjoy moisture-retentive conditions. Improve dry, sandy ground by digging in well-rotted manure. Mulch with bark. The hosta has good slug resistance but watch for damage to new leaves. In spring, cut the sedge back hard, as the regrowth is more colorful, and trim back the old flower stems of the stipa. Cut a few older bamboo canes at the base to maintain an open habit.

*Stipa gigantea*

*Phyllostachys aureosulcata* f. *aureocaulis*

*Yucca filamentosa* 'Bright Edge'

*Hosta sieboldiana* var. *elegans*

*Ophiopogon planiscapus* 'Nigrescens'

*Carex comans* bronze-leaved

# Easy perennials

With the right plants, you can sit back and enjoy fabulous flowering displays all summer long for next to no effort. This recipe combines colorful blooms and handsome foliage set off against the dark backdrop of a yew hedge. Relatively new on the scene, the blue cranesbill 'Nimbus' blooms from late spring to midsummer and is furnished with intricately cut foliage. Pincushion-flowered knautia takes over from mid- to late summer accompanied by tall spikes of the ornamental sage 'Ostfriesland'. The silvery felted lamb's ears (*Stachys*) and hairlike stipa make a textural foil.

## Border basics

**Size** 5 x 6 ft (1.5 x 1.8 m)
**Suits** Easy-care perennials and grasses
**Soil** Fertile, moist but well-drained
**Site** Sunny

## Shopping list

- 3 x *Geranium* 'Nimbus'
- 5 x *Knautia macedonica*
- 5 x *Salvia nemorosa* 'Ostfriesland'
- 3 x *Stachys byzantina* 'Silver Carpet'
- 5 x *Stipa tenuissima*
- *Taxus baccata* (hedge)

## Planting and aftercare

Cut the yew hedge toward the end of summer; leave a gap between the hedge and the border for access. Improve poor, dry soil with well-rotted manure, garden compost, or spent mushroom compost. This arrangement is best planted in spring or early fall. Mulch with bark to control weeds. The following spring, cut plants back to new growth arising from the base—none of them should require staking, but pushing a few twiggy sticks in around the cranesbill in spring will help stop plants from sprawling too far. Deadhead the knautia as often as you can to prolong flowering. Cutting back cranesbill foliage after flowering encourages compact, new leafy growth.

*Geranium* 'Nimbus'

*Knautia macedonica*

*Salvia nemorosa* 'Ostfriesland'

*Stachys byzantina* 'Silver Carpet'

*Stipa tenuissima*

*Taxus baccata*

# Contemporary prairie

This example of new wave or prairie-style planting is stylish and easy to care for. The ornamental sage, yellow foxglove, and verbena attract bees and butterflies, and if you leave this "meadow" to die down naturally, it will provide a valuable habitat for beneficial insects, small mammals, and birds. Flowering begins with the foxglove (*Digitalis*) and the violet-purple sage ('Mainacht' or 'May Night') in early summer, and reaches a peak in midsummer when the verbena joins the display. Giant feather grass (*Stipa*) throws up tall wands of glistening seedheads which, along with the verbena, last well into fall. You could consider maiden grass (*Miscanthus sinensis* 'Gracillimus') as a tall, narrow-leaved alternative to the stipa.

## Border basics

**Size** 8 x 8 ft (2.5 x 2.5 m)
**Suits** Grasses, natural-looking perennials
**Soil** Fertile, well-drained but not dry
**Site** Sunny, open

## Shopping list

- 5 x *Stipa gigantea* or *Miscanthus sinensis* 'Gracillimus'
- 9 x *Verbena bonariensis*
- 7 x *Salvia* x *sylvestris* 'Mainacht'
- 7 x *Digitalis lutea*

## Planting and aftercare

Plant in early fall or mid- to late spring, improving dry or poor soil by adding well-rotted manure or garden compost. Lay out the plants in large overlapping blocks or swaths and use the tall, "see-through" verbena at intervals between shorter plants to create a more dynamic and naturalistic arrangement. All of the plants can be left to die down naturally at the end of the season, as the old flower stems and seedheads remain attractive well into the winter. Trim back in spring but leave the evergreen grass tussocks.

*Stipa gigantea*

*Verbena bonariensis*

*Salvia* x *sylvestris* 'Mainacht'

*Digitalis lutea*

Alternative plant idea

*Miscanthus sinensis* 'Gracillimus'

# Aromatic herb border

Many traditional herb-garden plants have potential for use in low-maintenance plans, as they are mostly evergreen and drought-resistant. Here, aromatic lavender and common thyme blend with a cream-flowered cotton lavender (*Santolina*) and giant, silver-leaved cardoon (*Cynara*). Wispy bronze sedges weave through the planting, linking the various elements. The resulting slate-mulched bed has a muted, contemporary feel and would work well in full sun, adjacent to an open expanse of paving or decking. Add cream *Crocus chrysanthus* at the front for spring color.

## Border basics

**Size** 6 x 5 ft (1.8 x 1.5 m)
**Suits** Drought-tolerant herbs, perennials, and sedges
**Soil** Reasonably fertile, sharply drained
**Site** Sunny, sheltered from wind

## Shopping list

- 3 x *Santolina pinnata* subsp. *neapolitana* 'Edward Bowles'
- 5 x *Thymus vulgaris*
- 1 x *Cynara cardunculus*
- 5 x *Lavandula* 'Fathead'
- 7 x *Carex flagellifera*

## Planting and aftercare

Plant between spring and early summer, to give the herbs a chance to establish before winter. Improve the drainage of clay soils by digging in grit or gravel. Soak plants, remove pots, and set out to make a pleasing arrangement. For weed-free gardening, plant through membrane and mulch with slate chips or gravel. Clip over the lavender after flowering in late summer and, in fall, tidy up the faded leaves and woody flower stalk of the cardoon. The following spring, cut the cotton lavender back to a low framework, and lightly trim the thymes. Trimming the sedges close to the base in spring encourages colorful regrowth.

*Santolina pinnata* subsp. *neapolitana* 'Edward Bowles' ❄❄❄ 💧 ☼

*Thymus vulgaris* ❄❄❄ 💧 ☼

*Cynara cardunculus*
❄❄❄ 💧 ☼

*Lavandula* 'Fathead'
❄❄❄ 💧 ☼

*Carex flagellifera*
❄❄❄ 💧 ◑ ☼ ☼

# Chic foliage collection

The key to creating a contemporary look is to limit your plan to a single subject or just a handful of texturally interesting plants. Here the pink-leaved phormium adds height and vibrancy, its straplike foliage contrasting strongly with the bold, rounded leaves of the *Bergenia*. Flowering in spring, *Bergenia* 'Red Beauty' gives early-season interest and is followed by the simple white blooms of the convolvulus. An evergreen with leaves like strips of metal, the elegant convolvulus mirrors the silver container and complements the other plants, especially the "black" ophiopogon.

## Container basics

**Size** Galvanized metal container, approx. 16 in (40 cm) in diameter
**Suits** Architectural evergreen shrubs and perennials
**Soil** Loam-based, free-draining potting mix
**Site** Sunny, sheltered from hard frosts

## Shopping list

- 1 x *Bergenia* 'Red Beauty'
- 1 x *Ophiopogon planiscapus* 'Nigrescens'
- 1 x *Convolvulus cneorum*
- 1 x *Phormium* 'Jester'

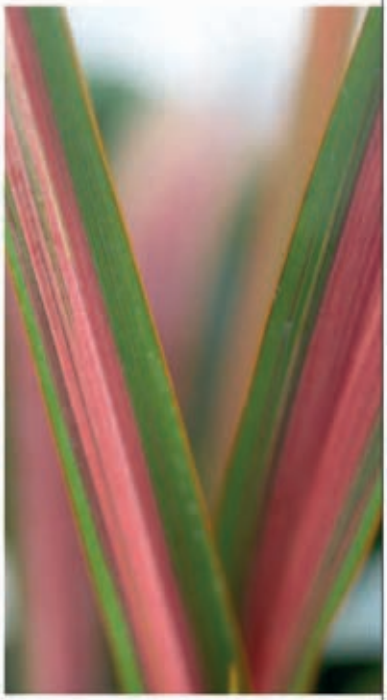
## Planting and aftercare

Metal containers heat and cool rapidly, potentially damaging roots, so insulate with a layer of bubble wrap or use a plastic pot as a liner, filling the gap with floating row cover. Cover the drainage holes with crocks and pour in 2 in (5 cm) of gravel. Half-fill with a good quality soil-based potting mix, adding slow-release fertilizer at the recommended rate. Arrange the plants to find the best fit, then plunge each pot into a pail of water, drain, and plant. Fill any gaps with more soil and water thoroughly. Water regularly, remove faded bergenia flowers, and renew fertilizer granules annually.

*Bergenia* 'Red Beauty'

*Convolvulus cneorum*

*Ophiopogon planiscapus* 'Nigrescens'



*Phormium* 'Jester'

# Cottage garden in a container

Plain or decorated, terra-cotta tends to fit in well with older historic properties and traditional types of gardens, such as formal or cottage style. When buying, check that the pots are guaranteed frostproof and have no visible cracks or chips; a bell-like ring when struck indicates that the pot is sound. Being porous, clay is ideal for herbs, alpines, succulents, and drought-tolerant plants; if you want to use other plants, and still cut down on watering, it is best to line the pots with plastic.

## Container basics

**Size** Terra-cotta pot, approx. 15 in (38 cm) in diameter
**Suits** Mediterranean-style perennials, herbs, and succulents
**Soil** Loam-based, free-draining potting mix
**Site** Sunny for most of the day

## Shopping list

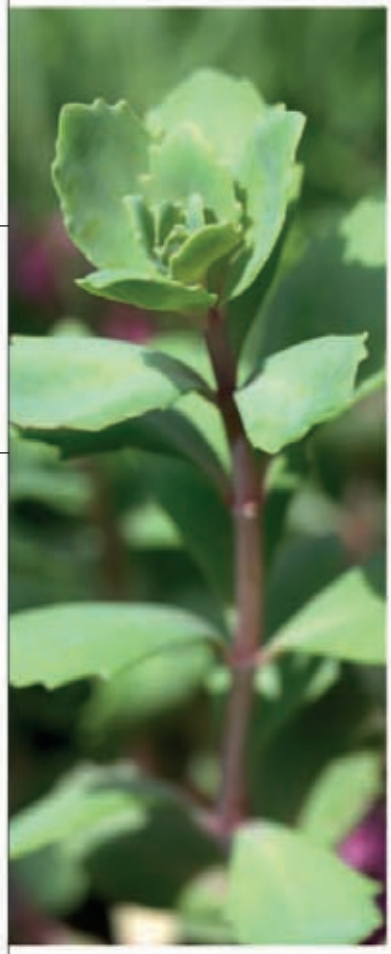
- 1 x *Lavandula angustifolia* 'Hidcote'
- 2 x *Scabiosa* 'Pink Mist' or *Osteospermum* 'White Pim'
- 1 x *Sedum* 'Ruby Glow'
- 2 x *Diascia* 'Sunchimes Lilac'

## Planting and aftercare

Soak the pot until the sides have turned a darker shade, indicating saturation, as this reduces the amount of moisture absorbed from the soil by the clay. Otherwise, line with black plastic, making sure that the drainage holes are uncovered. Protect the holes with fine mesh, flat stones or broken crocks, and add a layer of gravel for drainage. Half fill with loam-based mix combined with a slow-release fertilizer. After soaking the plants, arrange them to create a pleasing display. Carefully fill around the root balls, and finish at a final soil level 2 in (5 cm) below the rim to allow for watering. Regularly deadhead the scabious and diascia, and shear the lavender after flowering.

*Diascia* 'Sunchimes Lilac'

*Lavandula angustifolia* 'Hidcote'



*Sedum* 'Ruby Glow'

*Scabiosa* 'Pink Mist'

Alternative plant idea

*Osteospermum* 'White Pim'

# Tidying up your garden

A well-planned, easy-care garden can be spruced up in no time, especially if lawns have been replaced by low-maintenance surfaces, and borders contain plenty of evergreens and nonflowering plants that don't need deadheading.

## Garden facelift

During the growing season, weekly jobs, like mowing, deadheading, and sweeping, make a big difference to the look of the garden. Other tasks, such as hedge trimming and patio cleaning, as well as painting or refinishing various surfaces, may only be necessary once or twice a year. This "spring cleaning," however, is vital in easy-care gardens, where much more emphasis is placed on hard landscaping features. Shabby, mismatched fencing panels, peeling wall paint, faded decking, and paving slabs covered with algae catch the eye and mar your overall enjoyment. But if you have appropriate tools (some can be rented), you should be able to take care of such problem areas with ease.

**Vacuum outside** These handy but noisy tools allow debris, litter, and fallen leaves to be collected from paving and lawns, as well as from gravel and pebble surfaces, where it is difficult to use a brush.

**Better mowing** Maintain your own machine, or have it serviced regularly, to achieve the most efficient performance. Consider investing in a larger, more powerful mower if yours is too small for tackling the size of your lawn.

**Keeping hedges trim** Electric or gas-powered hedge trimmers are so much faster and less tiring to use than hand shears. To avoid raking up the debris, lay a tarp down to catch the trimmings.

**Lift off dirt** The strong jet of water produced by a pressure washer will lift grime and algae from paving, leaving a finish that looks like new. Test on a hidden corner first to make sure the surface won't be damaged.

**Instant makeover** Rolls of bamboo, willow, and heather screening can be used to cover mismatched fencing panels or ugly chain link for an instant and economical facelift. Attach with wire or plastic ties, or a heavy-duty staple gun.

**Easy cover-up** Repainting a wall freshens it up nicely, and applying a new color can add a designer touch to a patio or courtyard. After rubbing down the surface thoroughly, apply a quality exterior paint with a roller for ease.

**Protect your wood** Decking, fencing, trellises, and other wooden structures benefit from an application of all-weather paints, stains, and preservatives. Many companies offer special tools for speedy and efficient application.

## Informal pruning

Most gardeners love the appearance of a naturalistic, seemingly unpruned garden, brimming with flowers and foliage. Although the look can be achieved with the minimal amount of work, to create this informal style takes a little practice.

*Picture clockwise from left*

**Wild and free** The scene of roses growing in the garden of an old-fashioned country cottage typifies the naturalistic look but, despite appearances, regular pruning has achieved this effect. Long, leggy growths that spoil the shape of the rambler on the wall are cut back into the main body of the plant as soon as they are seen. In fall or early spring, the plant is given a gentle overall trim to keep its shape. A hard pruning is needed every three to five years.

**Beautiful berries** Firethorns (*Pyracantha*) make excellent informal, burglar-proof boundary hedges, their thorny stems keeping unwanted visitors at bay. These shrubs come into their own in fall when covered in berries, and are pruned lightly in spring. Take care not to cut back too much, or you risk losing the berries.

**Natural border** The success of this scheme is no accident; clever plant selection and a careful pruning regimen ensure its natural appeal. If left completely unpruned, one or two plants would become dominant and take over. The silver-leaved *Santolina* and golden sage are lightly trimmed annually, while the *Hypericum* 'Hidcote' is pruned every two or three years to maintain its shape. When in full bloom, the border looks like it has never been pruned.

**Color and texture** A good planting combination and the correct plant spacing ensures that this border of *Ceanothus* 'Puget Blue', Mexican orange blossom (*Choisya* 'Aztec Pearl'), and shrubby honeysuckle (*Lonicera nitida* 'Baggesen's Gold') needs only minimal pruning. If vigorous plants had been chosen or this selection had been placed too close together, the border would need much more work. The stems of the *Ceanothus* are shortened annually after flowering (*see p.335*) and the sideshoots of the *Choisya* and shrubby honeysuckle are removed every two or three years to keep them balanced.

# Pruning for a formal look

Trees and shrubs can be pruned and trained into many different shapes, and used to great effect in formal designs. Use them as focal points, to create views or backdrops, and to introduce shape and structure into the garden.

*Pictures clockwise from top left*

**Pleached effects** Trees such as lindens (*Tilia*) or hornbeams (*Carpinus*) can be trained into a structure that resembles a formal hedge on top of a series of straight trunks. This is achieved by training the branches horizontally so that they touch those of the next tree, which is trained in a similar fashion. Each year, the shoots that grow from these branches are pruned back to the main branch, resulting in a hedge with a distinctive structure. Use pleached trees to create high hedged effects or as a screen for a formal garden.

**Plant patterns** A parterre is made from hedges laid out in formal patterns and flowerbeds. The hedges can be of different heights and widths, and the designs intricate or simple. Plants used for a parterre must have a dense growing habit and be tolerant of close clipping, such as boxwood (*Buxus*) or yew (*Taxus*).

**Rose covering** Roses have been pruned and trained to cover the wooden supports that frame the view of the formal garden beyond. Mass plantings of hybrid tea and floribunda roses also add to the formal design.

**Elegant head** This beautiful shrub, *Viburnum rhytidophyllum,* has been pruned to create a stunning focal point. The lowest side stems have been removed, and the top allowed to form a branched head, which appears to float on its elegant "legs." This style of pruning can be practiced on many different plants but works best with evergreen shrubs.

**Leafy canopy** To create this leafy roof structure, several *Sorbus aria* have been trained so that the upper branches arch over to meet in the middle. No branches must be allowed to grow from the trunks, as this would spoil the effect, and those used to form the roof are pruned annually so the structure doesn't lose its shape. This eye-catching canopy takes many years to create.

## Pruning to create space

Plants are often pruned to keep them in check, but some delightful effects can be achieved with more imaginative techniques, like clearing lower stems of trees and shrubs to create elegant shapes and extra planting space beneath them.

*Pictures from left to right*

**Training standard bays** Lollipop shapes are very useful in a garden's design, as they create interest and structure. Plants that are pruned to create a bare trunk are called "standards." This technique is an excellent way of confining the size of large shrubs and creating space underneath for a bed of shade-loving plants.

**Tiny treelike wisterias** If left unpruned, wisterias are large climbers, but it is possible to restrain them with careful pruning. Fruit trees can be trained and pruned in a similar way to fit restricted spaces.

**Long-legged birches** The most beautiful feature of a silver birch (*Betula*) is its gleaming white stem. To show the trunks off to the best effect, remove the lower branches. This opens up planting spaces beneath, which are perfect for shade-lovers, such as these *Rodgersia*. This pruning technique can be used for any tree or shrub with attractive bark.

## Pruning to encourage flowering

Pruning plants correctly can increase the number of flowering shoots produced by the plant, giving you more flowers.

Knowing when and where to prune can make the difference between a poor show and a mass of color and scent.

*Pictures clockwise from left*

**Purple rain** A curtain of scented flowers in late spring, *Wisteria sinensis* needs to be carefully trained and spur-pruned each year in late winter to encourage flower bud formation (*see pp.172–173*). *Wisteria* grows very vigorously, so in midsummer, shorten the current season's growth by at least half, which also helps encourage the formation of flower buds.

**Snowy summer show** During early summer, *Philadelphus* 'Belle Etoile' is covered with large white scented flowers on arching branches. *Philadelphus* produces flowers on stems that formed the previous summer, so after it has flowered, remove about one-third of the oldest flowering stems, pruning them almost to ground level. Do this annually to help contain the overall size and shape of the plant and encourage plenty of new growth, which will be the flowering stems of the future.

**Rose heaven** Training a climbing rose, such as this *Rosa* 'Climbing Mrs. Sam McGredy', over supports shows off the blooms to their best effect. In late winter or early spring, remove approximately one-third of the oldest stems close to ground level. On the remaining older stems, spur-prune all the sideshoots and last year's flowering stems back to two or three healthy buds (*see pp.172–173*) from the main stem. Flowering growths will be produced from these spurs in the summer. At the same time, tie in strong new growth formed the previous year, which will need this support when they produce flowers.

**Less is more** *Clematis montana* is a vigorous plant, often grown over buildings and large plant supports. No pruning is required, but it may need trimming after blooming to keep it in check. In fact, some clematis are better left unpruned to encourage maximum flower production. In this instance, pruning reduces the volume of flowers that appear in late spring.

# Pruning for colorful stems and bark

Some trees and shrubs produce bold, colorful stems and bark, which can be enhanced by careful pruning to create dazzling effects, especially during the winter when the branches are bare.

*Pictures clockwise from top left*

**Bright highlights** Grown for its attractive white peeling bark, the birch *Betula utilis* var. *jacquemontii* is especially effective in the winter when silhouetted against an evergreen backdrop. When the tree is young, use pruners in early summer to remove the lowest small branches. Then, when the stem has reached the height at which you want the branches to form, allow them to grow but continue to remove the smallest side branches. This will give you a simple yet strong, distinctive branch shape, and a clean white trunk.

**Snakeskin decoration** Unusual white striations on the green bark of *Acer* 'White Tigress' give rise to the tree's common name—snakebark maple. To see these markings at their best, create a clear stem of between 4 and 6 ft (1.2–1.8 m) by removing the lowest branches with pruners annually, until you have the required length of stem.

**Show-stopping stems** The dogwood *Cornus stolonifera* 'Flaviramea' is grown for its outstanding winter stem interest, with different cultivars ranging from green to orange and dark red. This dogwood is most effective when grown in groups of two or three plants. To achieve the striking winter stem interest, prune the plants annually in early spring using pruners (*see pp.168–169*).

**Burnished bark** A member of the cherry family, *Prunus rufa* is grown for its ornamental mahogany-colored bark rather than its flowers, and is ideal for small gardens. The beautiful bark looks best when you can see through the branch structure. To achieve this, remove all the smaller and crossing branches from the main structure.

**Beautiful brambles** *Rubus cockburnianus* is an ornamental suckering bramble grown for its attractive winter stems, which are white and red in color. This plant is both a beauty and a beast—the stems are covered in thorns and make an almost impenetrable barrier, so you will need to wear gloves and eye protection when pruning. To attain the attractive winter stem color, cut the stems to the ground annually in early spring.

# Pruning for fruit

Fruit brings welcome color into the yard as well as edible treats. Fruit bushes and trees require a lot of pruning, but the blossoms and then the colorful and delicious fruit make it all worthwhile.

*Pictures clockwise from left*

**Colorful blueberries** The bushes of this popular fruit are of great value: they flower in the spring, fruit in the summer, and then provide lovely foliage color in the fall. Blueberries fruit on branches produced the previous year. Prune the bushes during the winter, removing two or three of the oldest stems each year, as well as any weak, dead, or diseased growths. Also remove any of the lower branches that may lie on the ground when laden with fruit in the summer.

**Decorative apples** Apple trees are beautiful in blossom and when covered in fruits. When choosing an apple tree for your yard, bear in mind that different varieties grow at different rates, so look for one that suits the size of your yard and the space available. Prune apple trees in the winter to give an open, airy structure. Do not prune too hard as this stimulates vegetative growth at the expense of flower buds and fruit.

**Productive pears** Pear trees are suitable for small yards if trained in a pyramid shape. To keep a tree small, reduce the length of the main leader (the tallest stem at the top of the tree) in winter. Also remove any congested growths during the winter when you can clearly see the skeleton of the tree. Then, in late summer, reduce the side branches by pruning them back to one leaf bud from the main stem. Pear trees will fruit without any pruning, but they can become too large for a small yard.

**Wall-trained espaliers** One of the most beautiful and artistic ways to grow an apple tree is to train it as an espalier against a wall, where pairs of branches are trained horizontally from the central stem. Apple espaliers are suitable for small yards, but require great care and maintenance. During the late summer, prune all the sideshoots, taking each one back to the first noticeable leaf above the main horizontal branch. As the plant grows older, the branches that produce fruit will become crowded and will then require thinning in the winter.

# Choosing pruning tools

Using the right tool for the right job is one of the most important factors when pruning. Choose your tools carefully and look for good-quality products that are safe to use and make sharp, clean cuts that won't damage your plants.

**Pruners** There are two types of pruners: anvil (*above*) and bypass (*right*). The cutting blade of anvil pruners presses down onto a metal block edge, while the bypass's cutting blade passes the bottom blade in a scissor action. Bypass pruners give a cleaner cut and are easier to use. Only use pruners for cutting stems less than ½ in (1.5 cm) in diameter.

**Pruning saw** An essential tool, this saw has either a folding or fixed blade that can be replaced when it is worn or damaged. Pruning saws are good for awkward situations.

**Long-armed saw** Use this saw for cutting small branches above head height. Always wear eye protection and a safety helmet, and save large branches for the professionals.

**Bow saw** Only use this tool for cutting branches that have already been pruned and removed. The shape makes it unsuitable for use in difficult and awkward situations.

**Loppers** Often used for pruning branches that are too thick for pruners—although a pruning saw is the ideal tool—or for reducing the length of branches and stems. When using loppers, don't employ excessive pressure, as you can easily twist and crush the pruned stem.

**Long-armed loppers** If you need to shorten stems, or remove dead or diseased material that is above head height, this is a useful tool. Never use long-armed loppers to cut stems more than 1 in (2.5 cm) in diameter as they can be quite difficult to control.

**Electric hedge trimmer** Useful for cutting most types of hedges. Always work from the bottom to the top, make sure the cord is behind you, use a GFI outlet, and never use in damp or wet conditions. Wear ear protection and read the instructions before use.

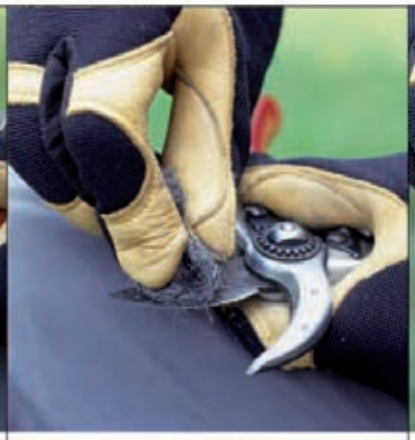
**Gas hedge trimmer** Usually much heavier than electric types, gas trimmers can be tiring to use for long periods. They will saw through most hedges, and are useful for cutting those with thick sideshoots. Always wear ear protection and read the instructions carefully.

# Tool care and safety tips

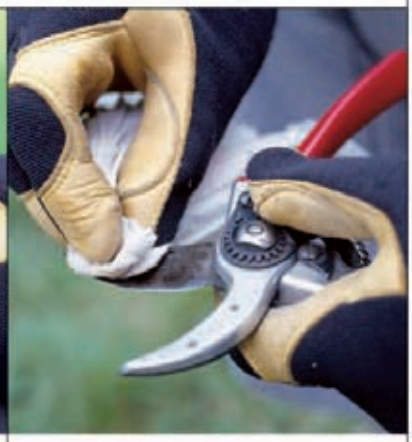
Using the right pruning tools and correct safety equipment helps to ensure that pruning is safe and enjoyable. You will also protect yourself against accidents if your equipment is well maintained, and extend the life of your tools.

## Cleaning pruners

1 When pruning, plant sap dries and sticks to the blades, making them stiff. Scrape off the sap using a piece of metal with a straight edge, such as a metal plant label or penknife.

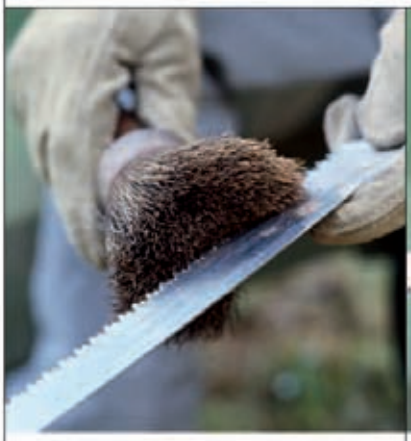


2 Then rub the blade with steel wool to remove any remaining dried sap and rust or other material. To prevent accidental cuts, wear gloves while cleaning your blades.



3 When the blade is clean, rub on some lubricating oil. This guards against rusting, and keeps the pruners sharp and clean while they are being stored.

## Cleaning pruning saws



1 When you have finished pruning, use a coarse brush to remove any sawdust lodged in the saw's teeth. If this is left, it can harden and reduce the saw's cutting ability.

2 Next, use steel wool to rub both sides of the saw blade. This removes dried sap and dirt, which can also make the saw less efficient.

3 Before putting the saw away after cleaning, rub some lubricating oil onto it with a cloth to protect the blade from rusting.

**Wear gloves** Always wear sturdy gloves when pruning to protect your hands from sharp tools, and from cuts and scratches caused by thorny or sharp-edged plants.

**Use protective goggles** Protect eyes from dust, sawdust, and plant trimmings, especially when working above head height. Goggles also protect against thorns and shoots.

**Keep electric wires behind you** When using electric hedge trimmers, ensure that the cord is behind you so you cannot cut through it, and plug it into a GFI outlet.

**Making ladders safe** Use a tripod ladder, and ensure it is stable by fully extending the legs. Don't over-stretch or lean out to either side. If possible, ask someone to stand at the bottom.

**Using platforms and ladders** Before using this equipment, ensure that each set of legs is on level ground and adjust if not. Do not over-stretch or lean out too far on either side.

**Pruning your neighbor's plants** Before pruning plants that are overhanging your yard, speak to your neighbors. You are more likely to reach an agreement about how much to cut off if you maintain a good relationship. However, branches that overhang your yard may be classed by law as trespassing on your space, and you may have the right to cut them back to your boundary; check the laws in your state or province before you start. The branches that you have cut and any fruit that was on them should then be returned to your neighbor. You are not allowed to enter your neighbor's property, or to lean over it to prune your hedge, without seeking permission first.

**The dangers of chain saws** Always call in a trained arborist to cut down large branches that can be only safely removed with a chain saw. Do not attempt to use one yourself.

# Essential pruning jobs

Most pruning tasks are performed annually, but those outlined here need immediate attention and are best tackled as soon as problems are seen.

**Crossing and rubbing branches**
Branches that have grown too close together and are rubbing against each other are a common problem. If you spot these, remove one of the branches, either the weakest one or the stem that has suffered the most damage. Branches that rub each other can create open wounds through which disease may enter the plant, causing serious problems.

## Removing suckers

A sucker is a vigorous strong growth that emerges from a point low down on a plant, close to the root system. If left, it can choke the plant or reduce its vigor. Such shoots are normally found on plants that have been grafted, such as roses, and usually look quite different from the rest of the plant. If seen early, remove such a shoot by quickly tugging it away with a gloved hand, or if it has grown too large, remove the shoot using pruners.

A sucker growing from below the graft (knobby bulge) on a rose

## Cutting out reverted leaves

Reversion is when the leaves of a variegated plant turn pure green. If left to grow, these green shoots, which have greater vigor, can take over and ruin the appearance of the plant. When you see any shoots that are showing signs of reversion, remove them completely using pruners, and make sure that you prune back to where the shoots are still all variegated. This can be done at any time of the year.

Remove green shoots from variegated plants like *Euonymus* cultivars

## Dealing with twin leaders

Twin leaders occur at the top of a tree when two stems of similar vigor are growing close together. Remove the weaker stem using pruners. If left unpruned, the stems will try to grow away from each other, causing a weakness to develop. One stem may then break away from the tree, causing serious damage. Although this may not happen until the tree is much older, prompt action when the plant is young will prevent future problems.

Remove the weaker stem

A single leader has strength

## Limiting frost damage

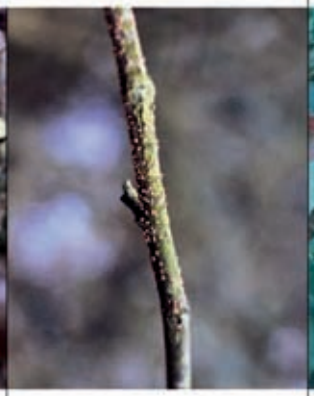
Buds and young shoots can be damaged when caught by spring frost. Prune plants back to healthy, unfrosted buds to prevent dieback or diseases from starting at the frosted points. Most plants will then produce new growths lower down the stems. However, on some plants, such as *Hydrangea macrophylla*, frost may damage all the new flower buds produced on the previous season's growth, and you will lose the coming year's blooms.

*Hydrangea macrophylla* 'Libelle' with frost damage

## Cutting out dead and diseased wood

Whenever you see dead or diseased wood on any tree or shrub, remove it immediately. If dead wood is left on a plant, disease can enter more easily and it may move down the stems, attacking healthy growth. Dead wood also looks unsightly. When a tree or shrub has been damaged, its natural defenses will eventually form a barrier in the form of a slight swelling between the live and dead wood. In this instance, remove the dead wood above the barrier.

Dead wood on a hornbeam



Coral spot on a branch

## Deadheading to promote flowering

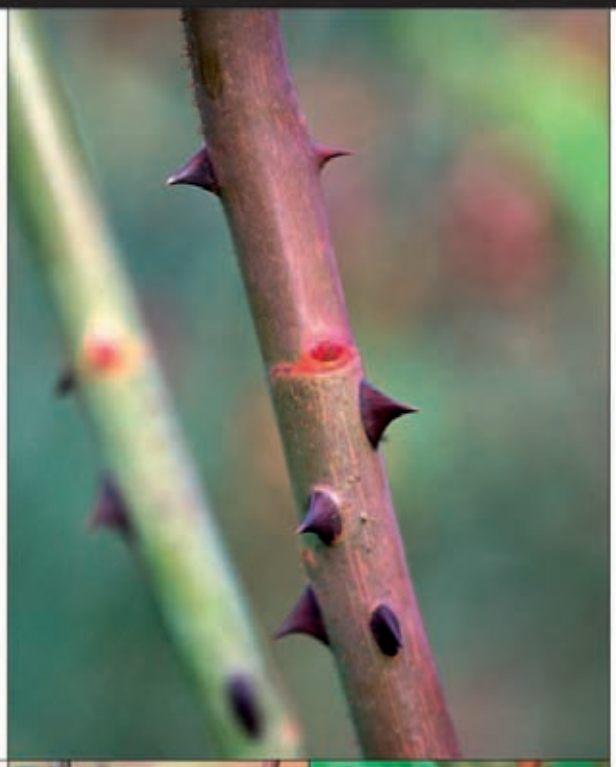
The removal of dead flowerheads can encourage many repeat-flowering plants, like roses, to produce more blooms. These dead flowers can be snapped off with the fingers, or removed using pruners. On some shrubs, like rhododendrons, removing the dead flowers encourages the plant to produce more stems, rather than wasting its energy on making seeds. This enables the plant to produce more flowers the following spring.

A dying rose bloom can be easily snapped off by hand

# Making pruning cuts

Trees, shrubs, and climbers grow in many different ways, and their shoots, buds, and stems may look completely different too. To avoid confusion, before you start pruning, try to identify the position and type of buds and shoots on your plant, and then make your cuts.

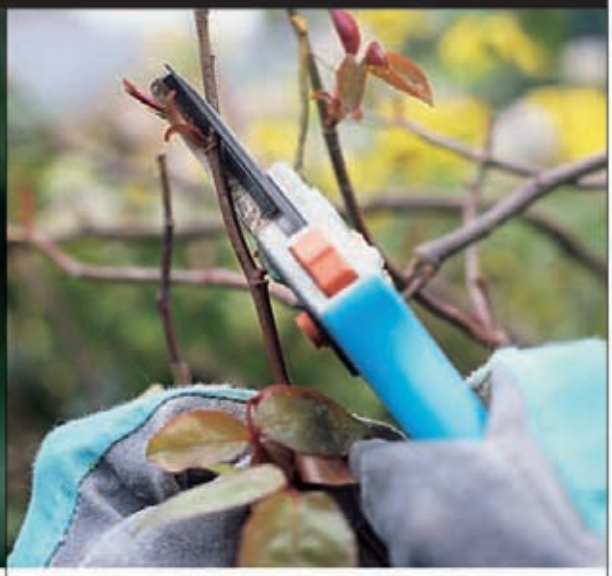
**Identifying a shoot bud** Buds come in many different shapes, sizes, and colors. Some are slight swellings or raised bumps on the stems; others may be a different color from the rest of the stem, such as rose buds (*see right*). Buds are always produced at the point where leaves are growing, or have previously been attached to the stem. When pruning, you always cut immediately above a bud, which stimulates hormones in the plant to make the bud develop into a new stem.



**Pruning to a new shoot** A new shoot is normally light green in color and looks quite obvious, as on the clematis shown here. New shoots can be quite soft and delicate, and you have to be careful not to damage or break them when pruning back to the new growth.

**Pruning to new growth** You can recognize the new growth on a plant because it looks much fresher than old wood. When pruning, cut off the old wood just above a new stem, using a sloping cut so that excess moisture runs away from the young growth.

**Cutting opposite buds** The buds of some plants, such as dogwoods (*Cornus*) and hydrangeas, are opposite each other. Prune immediately above a pair of buds with a flat, straight cut. When the buds grow, they will produce two shoots growing in opposite directions from one another.



**Cutting alternate buds** The buds of plants such as roses and wisteria grow alternately along the stems. Try to prune to a bud that is facing outward, away from the center of the plant. Make a sloping cut immediately above the bud, so that excess moisture runs away from the bud.

**Using a pruning saw** If the stem you intend to prune is thicker than a finger, use a pruning saw to make the cut. Many stems are spoiled by attempting to cut them with incorrect tools. Pruning saws make a much cleaner cut than loppers. Always wear protective gloves.

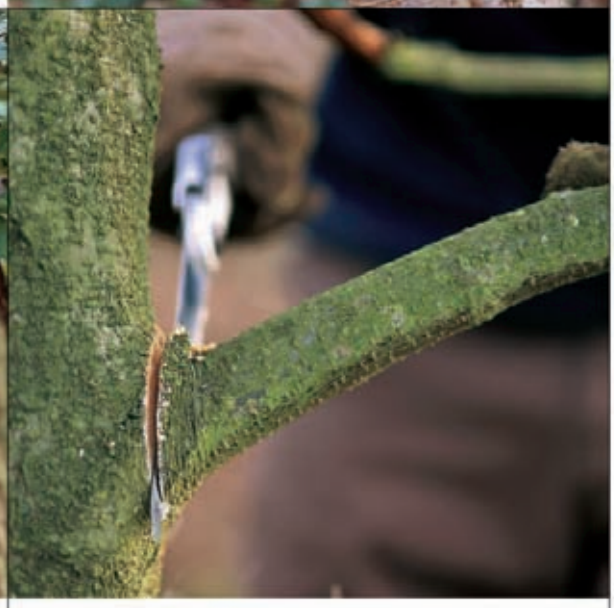
**Shearing** When cutting shrubs or hedges with a dense habit, such as yew (*Taxus*) or boxwood (*Buxus*), hand shears are the best tool for the job. Shears are also very useful for trimming lavenders and heathers. Make sure the shears are sharp and clean so you get a good clean cut.

# Removing branches

It is very important to remove a branch correctly. Bad or rough cuts can reduce a plant's ability to heal itself, which may then allow disease to enter the wound. Eventually this can cause rotting, reducing the plant's life span.

**Hard to reach branches** Branches that are difficult to reach can lead the person who is pruning to take shortcuts. Mistakes are more often made when one is attempting to prune from a distance. If the branch that needs to be pruned cannot be reached safely by a ladder, seek the help of a trained and experienced arborist. If a small branch is not too high, it may be possible to prune it with a long-armed lopper or pruning saw, following the same procedure shown opposite.

**Torn branches** A heavy branch is likely to tear when being pruned, as its weight will pull down the stem and rip it before you can complete your cut. If you don't have someone to hold the branch while you prune it, shorten it in stages before attempting the final cut. Also make an undercut first (*see Step 1, facing page*), which helps to prevent tearing when you cut through it from above.



**Bad cuts** Never cut flush to the trunk of the tree, as this removes the tree's own healing system. It can look tidy to begin with, but the stem will not heal properly, and the open wound may then allow disease to enter the tree. Cutting branches flush with the trunk is one of the major causes of decay and ultimately death in trees.

## How to remove a branch

1 Reduce the weight of a heavy branch by cutting it back to leave a 6-in (15-cm) stump. Then make the final cut. To prevent tearing, first make an undercut where the branch starts to swell or 1¼ in (3 cm) from the trunk.

2 Stop cutting when you are about halfway through the branch. Then make another slightly angled cut from the top, just behind the crease in the bark where the branch meets the trunk. Be sure the upper cut meets the undercut.

3 This pruning method results in a clean cut, and preserves the "collar," part of the plant's healing system. The cut surface will begin to shrink as the tree produces protective bark, which will eventually cover the exposed area.

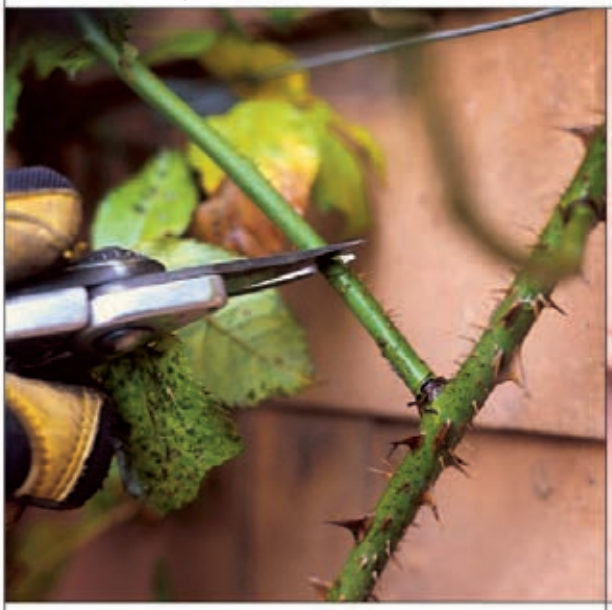
### Tip for success

When cutting a heavy branch, ask someone to help support the weight when you saw. This helps to prevent tearing. It can also stop the branch from swinging or falling, and damaging the plant being pruned or injuring the person who is pruning.

## Spur pruning

Spur pruning encourages bud formation on trees, shrubs, and climbers. Where this rose has been spur-pruned, it has produced three new stems, each of which will flower.

## Spur-pruning a rose



To spur-prune a climbing rose, find a healthy sideshoot growing from one of the main stems. Count two or three buds from the stem along the shoot. Make an angled cut immediately above this second or third bud, sloping away from it. Repeat farther up the main stem.

After pruning, you will be left with short growths, which are described as "spurs." From the buds on these spurs, two or three flowering stems will emerge, depending on how many buds were left on the spur.

## Spur-pruning wisteria

Spur-prune wisterias in late winter. Using pruners, shorten each new shoot that has grown the previous season, so that two or three healthy buds remain. Always make the cut immediately above the outermost bud and sloping away from it.

This picture shows the stems once they have been shortened to two or three buds. The buds on the short spurs will swell to produce flowers or flowering stems in late spring and early summer, producing cascades of sweetly scented purple or white blooms.

# Pruning hydrangeas

*Hydrangea paniculata* flowers in late summer on stems it has made that same year. To keep the plants compact, prune in early spring to promote new flowering wood. This also encourages larger flower panicles in the summer.

*Hydrangea paniculata* is an elegant plant with wonderful large conelike flowerheads. Most have white flowers, but there are also cultivars that are tinged with pink. They make excellent shrubs for the late summer garden.

1 In late winter or early spring, prune last season's stems to one or two buds from their base. Also take out any dead, diseased, crossing, or weak branches.

2 Any large, unhealthy branches should be cut back to healthy wood or to the base using a pruning saw. This prevents disease from spreading to the rest of the plant and promotes the growth of new, vigorous stems.

3 After pruning, you will be left with an open framework of branches. These will produce a mass of growth during the summer and an abundance of beautiful white flowers.

*Hydrangea macrophylla*, or florist's hydrangea, flowers in summer from buds that have already been set the previous summer. These buds are prone to frost damage in the spring months, and plants need careful pruning.

*Hydrangea macrophylla* produces sumptuous large flowerheads in blue, pink or white during the summer months, before *H. paniculata*. To ensure a good display, the developing flower buds need some frost protection throughout winter.

1 The hydrangea's old flowerheads help to protect the delicate new flower buds from frost, so leave them on the plant during the winter months. The dried flowers also add structure and interest to the winter garden.

2 When the danger of hard frost has passed in late spring, remove the flowerheads by pruning the stems back to a pair of healthy buds, as shown.

3 Do not be tempted to prune too hard, as this will remove many of the flower buds, which will have already formed on the stems that grew the previous year. New stems that grow in the coming year will bloom the following summer.

# How to prune a smoke bush

Grown for their outstanding summer and fall foliage, and tiny, cloudlike flowers, smoke bushes (*Cotinus*) are best pruned annually in the spring.

**Other plants to prune this way**

- *Catalpa bignonioides*
- *Cotinus coggygria*
- *Rhus chinensis*
- *Rhus typhina*
- *Sambucus nigra*
- *Weigela* 'Praecox Variegata'
- *Weigela* Wine and Roses

## Foliage effects

Pruning hard encourages the plant to produce larger, more decorative leaves, although you may lose the smokelike blooms.

1 Mature smoke bushes can outgrow their allotted location and suffer from dieback. Both problems are easily remedied by cutting plants back hard in the spring before the leaves appear.

2 First, remove any dead growth using a pruning saw. Also cut out diseased stems, taking them back to healthy growth. When removing large branches, cut them back in stages to ensure that they do not tear.

3 To keep a cotinus small and compact, cut back all of the taller branches to about 2 ft (60 cm). Prune to healthy wood, which you can identify by checking that it is green in color beneath the bark, and make sloping cuts.

4 Continue around the plant until you are left with a core structure of stems, each no higher than 2 ft (60 cm). New growth will soon start to sprout, resulting in plenty of fresh foliage that will provide exciting fall color.

# Pruning witch hazel

With their fragrant, spidery flowers, witch hazels (*Hamamelis*) are wonderful shrubs in winter, but if left unpruned, they can become too large for a small garden.

## Tip for success

Prune witch hazels just as the flowers are fading but before the leaves unfurl. Cut just above a healthy young sideshoot.

1 To reduce the size of this plant, in early spring prune back the taller branches by 12–20 in (30–50 cm). Try to keep in mind the overall shape you are aiming to achieve.

2 While pruning, step back occasionally to look at what you have cut out, and what still needs to be done. Always prune out old stems, leaving healthy young growth.

3 Occasionally you may find some crossing branches in the center of the bush that are difficult to reach. If a branch is awkwardly positioned, it may be easier to cut upward from below the branch.

## Tip for success

If you are not sure how much to remove, reduce the length of the stems a little at a time. Stand back, and then prune more if needed, until you have created an attractive overall shape.

# How to prune shrubby honeysuckle

Prune winter-flowering shrubs, such as *Lonicera x purpusii* 'Winter Beauty', in early summer. Remove the oldest flowering stems to encourage new, strong shoots to grow from the base.

## Tip for success

It is much easier to use a pruning saw to cut through branches that are too thick for either loppers or pruners.

1 First, reduce one-third of the oldest stems on the plant. Use loppers to cut back their length by about half, thereby decreasing the weight of the stem and preventing tearing, before you make the final cut closer to the ground.

2 With the loppers or a pruning saw, cut back to 12 in (30 cm) above the ground the stems that you have already pruned by half. Make a sloping cut immediately above a sideshoot to allow rain to run off the cut surface.

3 Using pruners, shorten the tallest of the new stems, which may be over 6 ft (1.8 m) high, by several inches (centimeters). This encourages buds farther down the plant to shoot, creating a bushier plant with more flowers.

4 When you have finished pruning, you should still have some older stems that will produce flower buds the following winter. The strong young growths coming from the base will now have more room to develop.

# Hard-pruning a camellia

Evergreen shrubs, such as camellias, that have outgrown their position can be hard-pruned in late spring or summer, just after they have finished flowering.

**Other plants to prune this way**

- *Aucuba japonica*
- *Elaeagnus pungens*
- *Erica arborea*
- *Escallonia*
- *Fatsia japonica*
- *Prunus laurocerasus*
- *Prunus lusitanica*
- *Viburnum tinus*

New growth

A year after pruning, the plant will have produced a mass of young stems but may not flower for a further two or three years.

1 This plant has outgrown its location and now needs to be cut back hard. Camellias respond very well to severe pruning, a task best performed immediately after they have finished flowering in late spring or early summer.

2 Use a pruning saw to reduce the height of the plant. To prevent tearing, cut back large, heavy branches in stages, rather than cutting off long sections.

3 Loppers are ideal tools for pruning back awkwardly placed side stems, allowing you to reach them more easily. But the final cut close to the main branch must be made using a pruning saw, as it gives a cleaner cut.

4 Aim to reduce the plant's height to about 24 in (60 cm). By the time you are finished, the camellia will resemble a small wooden stump, but it will not take long for new shoots to start growing (*see opposite page*).

# Cutting back California lilacs and philadelphus

Most California lilacs (*Ceanothus*) have vivid blue flowers in early summer. If left unpruned, they can become large and untidy, but if cut back too severely, the plant will not regenerate. Prune immediately after flowering is finished.

1 Here you can see an evergreen *Ceanothus* in full bloom in early summer. To maintain its compact shape, it will need to be lightly pruned later in the summer, after it is finished flowering.

2 After flowering, you can more clearly see the branch structure of the plant. To keep it in good shape, cut back long, untidy branches by 9–12 in (22–30 cm), but leave some of the shorter stems unpruned.

3 Use pruners to prune the branches, and make each cut immediately above a leaf bud. This will encourage the plant to produce growths from below the cut, resulting in a compact branching structure.

4 After pruning, the overall size of the plant is reduced, but it has not been cut back too severely, which would weaken it. If pruned like this annually, the *Ceanothus* will remain neat and bushy, suitable for a small garden.

*Philadelphus* has white, scented flowers in early summer. Prune the plant after flowering to encourage the formation of new growths, which will bear flowers in the future. An annual pruning also helps to contain the size of the plant.

1 In early summer, mock orange (*Philadelphus*) is a mass of white scented flowers. As soon as flowering is finished, cut back about a quarter of the oldest flowering stems to 6 in (15 cm) above the ground.

2 Cutting back hard some of the oldest stems promotes the formation of new shoots below the pruning cut, but do not be tempted to remove all the old stems, as this will reduce the volume of flowers the following summer.

3 Check the remaining old stems for young growths. These are best shortened rather than being hard-pruned. Take off the top third of these young stems, and prune them back to new wood.

4 Finally, trim the tips of any strong young stems that are already present in the plant—some may be as tall as 8 ft (2.5 m). This encourages them to branch lower down, which results in more flowers.

# How to prune a patio rose

Patio roses are small, repeat-flowering plants that can be grown in borders or containers. Prune them in early spring to encourage a mass of new shoots that will flower in the summer.

## Tip for success

As well as pruning your rose every year, encourage it to keep flowering for longer by removing the blooms as they fade.

1 The aim of pruning is to reduce the plant's height by one-quarter to a half and to create an open shape. Cut back the outer stems, and then remove dead, diseased, and damaged growths, plus any weak or crossing stems.

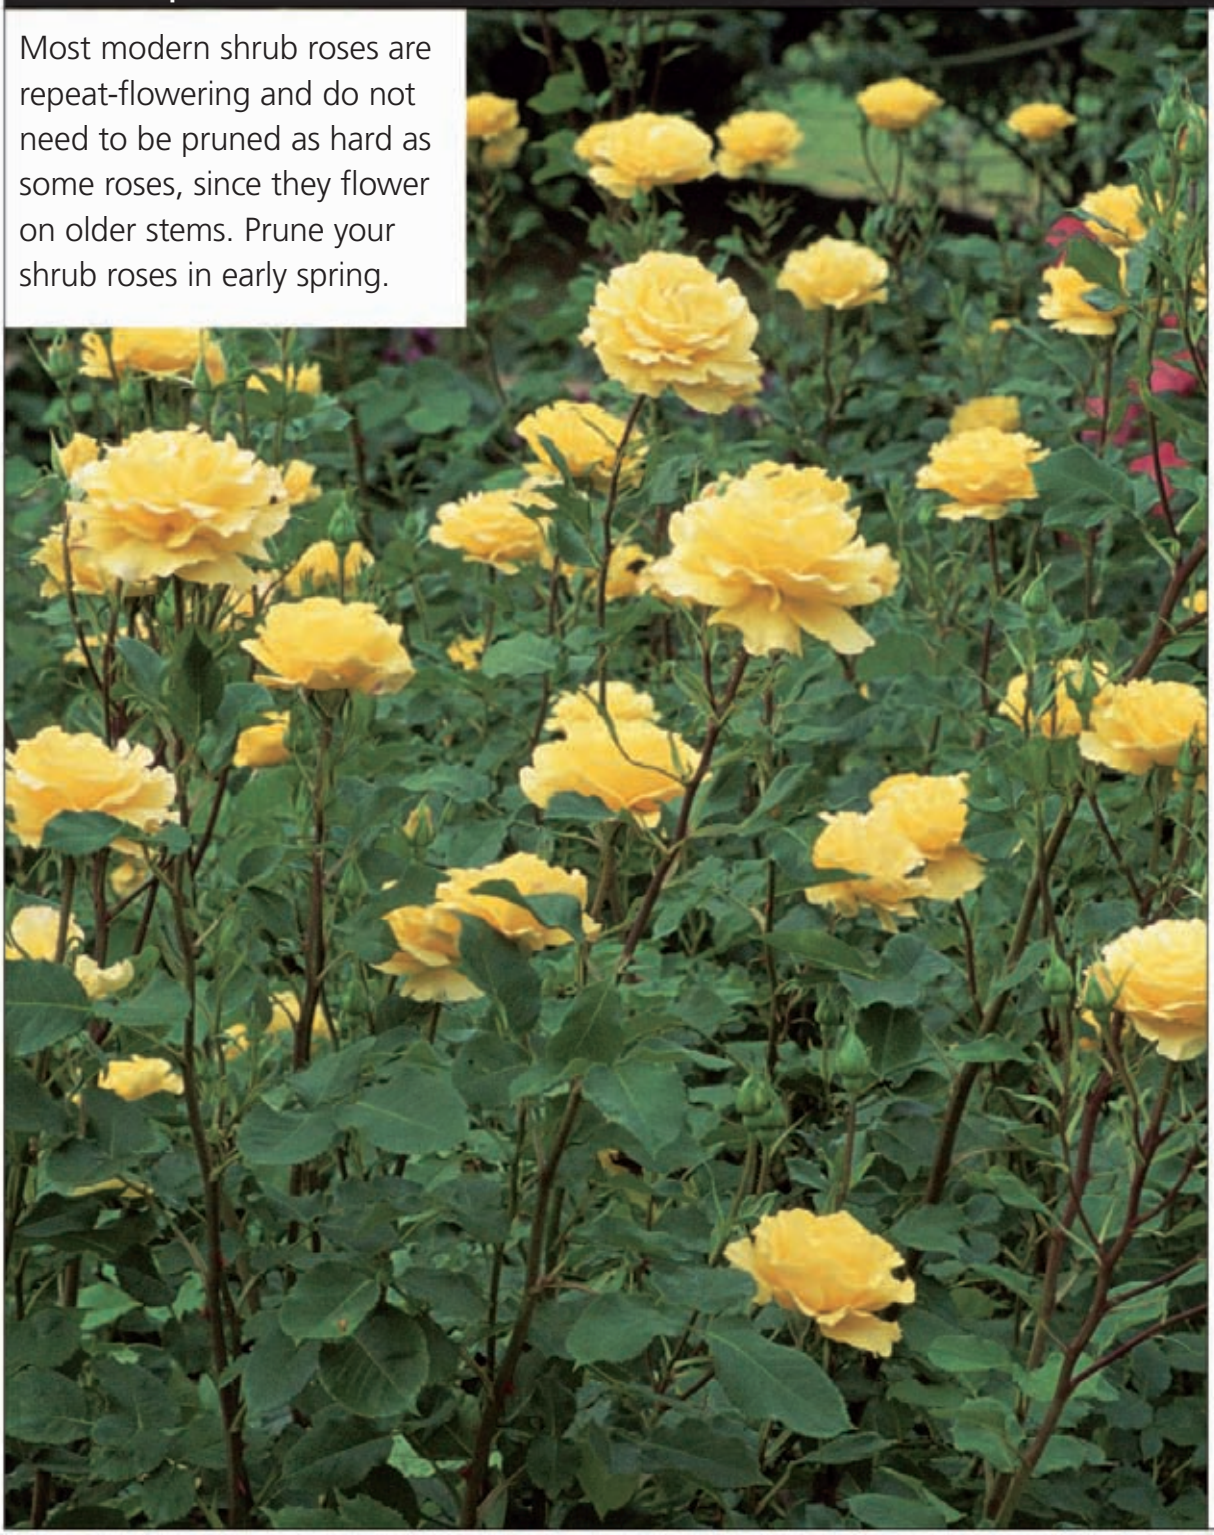
2 Always prune above a strong outward-facing bud if possible. Ensure that the cuts are sloping so that rainfall runs away from the bud, reducing the chance of its rotting.

3 This strong stem is being cut back by one-half, which will encourage many strong flowering shoots to grow from it in the forthcoming summer.

4 As well as producing more flowering stems, the resulting simple framework allows air movement, which reduces the incidence of fungal diseases. Fertilize and mulch roses after pruning to further encourage healthy growth.

## How to prune a shrub rose

Most modern shrub roses are repeat-flowering and do not need to be pruned as hard as some roses, since they flower on older stems. Prune your shrub roses in early spring.



1 The aim of pruning a shrub rose is to create a strong structure and to remove congested stems that were produced the previous year. This improves air flow through the plant, which helps prevent fungal diseases.

2 Cut off any dead, damaged, or diseased branches. Then remove any weak shoots not strong enough to support new flower growths. Also prune a few of the oldest stems down to the ground.

3 Reduce healthy main stems by a quarter, and prune some of the sideshoots by just a few inches (centimeters). Always cut above a healthy bud that faces outward, away from the center of the plant, if possible.

4 The pruned plant should be reduced in height by about a quarter, and have a strong, open structure that appears uncluttered in the center. By midsummer the plant should be covered in beautiful blooms.

# Pruning other types of roses

Different types of roses have different pruning needs. Identify your roses and then follow these guidelines to ensure that yours produce their best show.

### Old garden roses

These roses normally have one flush of flowers each year. Prune in early spring, first removing any dead, damaged, diseased, weak, or crossing branches. They do not need severe pruning: aim to reduce the size of the plant by one-third. Always make a sloping cut above an outward-facing bud. In the fall, cut back the stems by one-third to reduce the risk that wind will rock the plant and damage the roots.

**Examples of old garden roses**

- *Rosa* 'Blanche Double de Coubert'
- *Rosa* 'Boule de Neige'
- *Rosa* 'Charles de Mills'
- *Rosa* 'De Rescht'
- *Rosa* 'Fantin-Latour'
- *Rosa* 'Frau Dagmar Hartopp'
- *Rosa* 'Louise Odier'
- *Rosa* 'Madame Isaac Pereire'
- *Rosa* 'Madame Pierre Oger'
- *Rosa* 'Maiden's Blush'
- *Rosa mundi*
- *Rosa rugosa*
- *Rosa rugosa* 'Alba'
- *Rosa* 'Souvenir de la Malmasion'
- *Rosa* 'William Lobb'

### Hybrid tea roses

This group of roses normally flowers more than once during the summer months. They respond well to hard pruning in early spring. First remove all dead, damaged, diseased, weak, or crossing stems, and then prune out the oldest stems, taking them back to the ground. Leave between three and five young, strong stems, which should be pruned to a height of 6 in (15 cm) above the ground. As a guide, stand your pruners on the ground, and as these are normally about 6 in (15 cm) long, they will show you how far to prune back the stems. Always make a sloping cut above an outward-facing bud, if possible. In late fall or early winter, reduce the height of the stems by one-third to reduce the risk that wind will rock the plant and damage the roots.

**Examples of hybrid tea roses**

- *Rosa* Alexander
- *Rosa* 'Blessings'
- *Rosa* Dawn Chorus
- *Rosa* 'Deep Secret'
- *Rosa* Elina
- *Rosa* Freedom
- *Rosa* Ingrid Bergman
- *Rosa* 'Just Joey'
- *Rosa* Lovely Lady
- *Rosa* Paul Shirville
- *Rosa* Peace
- *Rosa* Remember Me
- *Rosa* Savoy Hotel
- *Rosa* 'Silver Jubilee'
- *Rosa* Tequila Sunrise
- *Rosa* Troika
- *Rosa* Warm Wishes

### Floribunda roses

Floribundas are repeat-flowering roses that produce clusters of blooms during the summer months. Pruning is very similar to hybrid tea roses, but not quite as hard. First, remove all dead, damaged, diseased, weak, or crossing stems. Your aim is to leave a framework of between six and eight of the strongest, youngest stems. Prune them to a height of between 8 and 12 in (20–30 cm), always make a sloping cut just above an outward-facing bud, if possible. In the fall or early winter, reduce the height of the stems by one-third to reduce the risk of damage if wind rocks the plant and disturbs its root system.

### Examples of floribunda roses

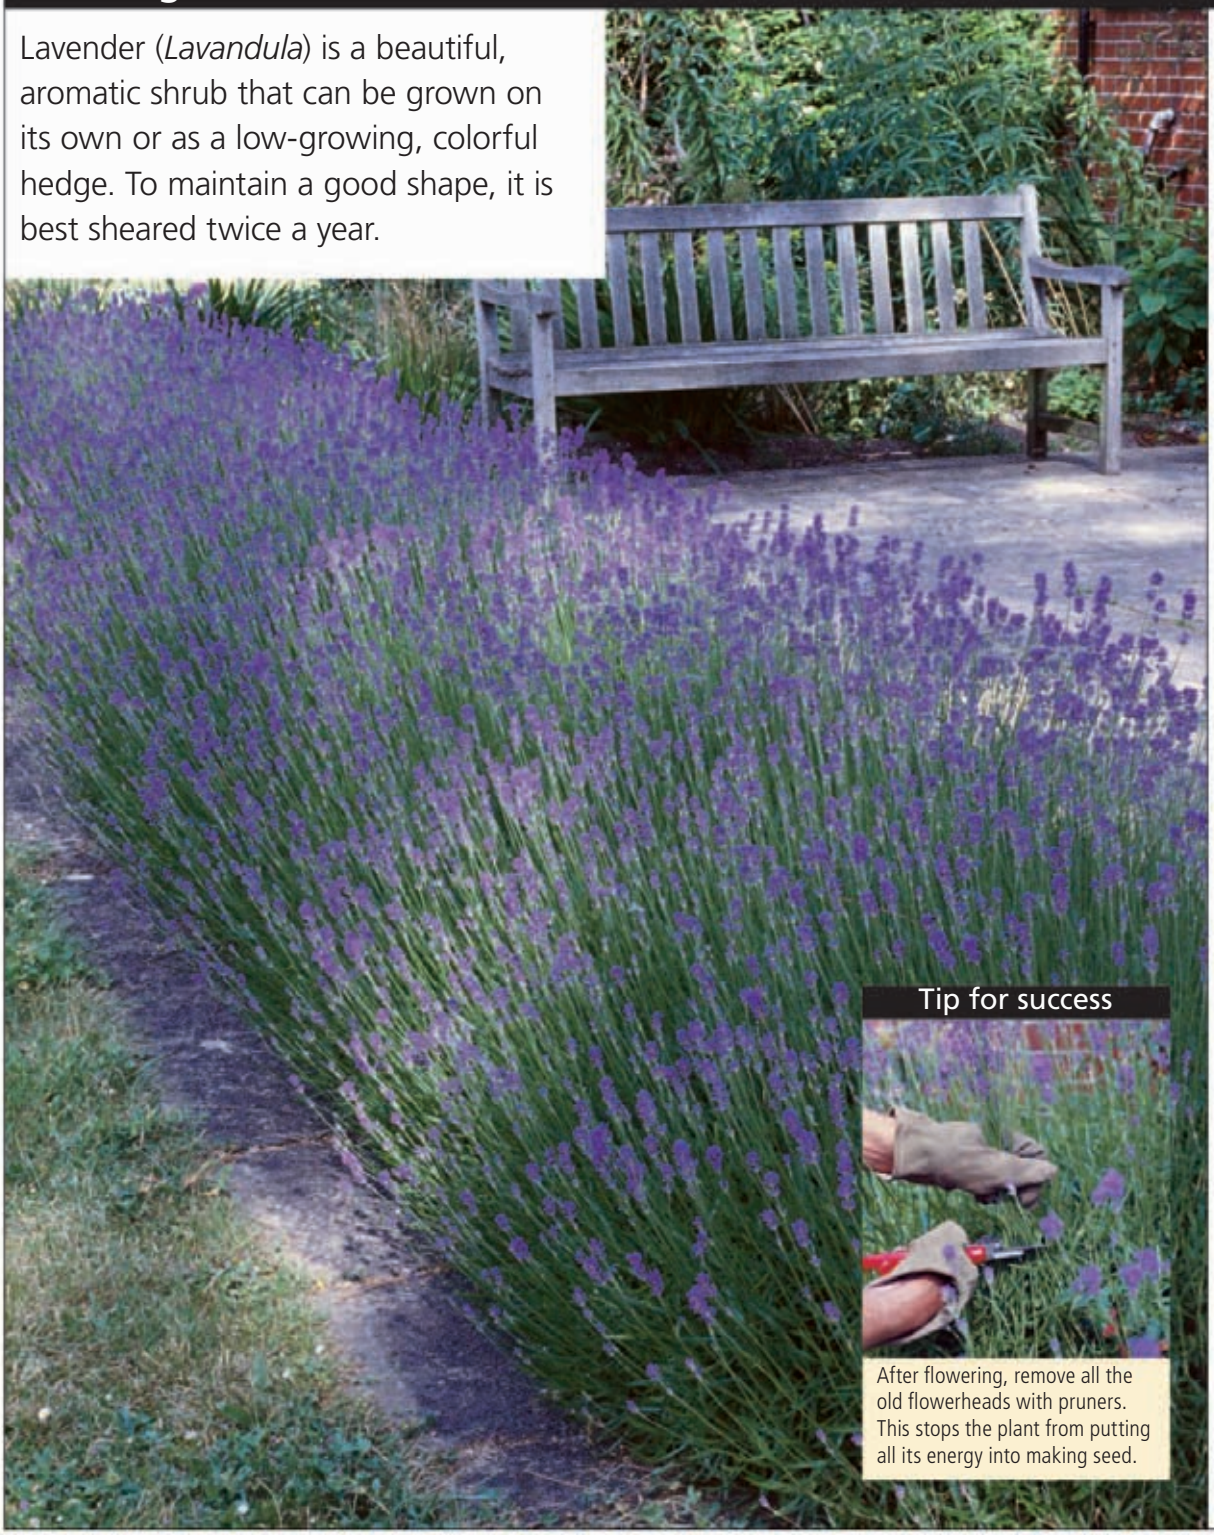
- *Rosa* 'Arthur Bell'
- *Rosa* 'English Miss'
- *Rosa* Fascination
- *Rosa* Fellowship
- *Rosa* 'Fragrant Delight'
- *Rosa* Iceberg
- *Rosa* Memento
- *Rosa* Pretty Lady
- *Rosa* 'Princess of Wales'
- *Rosa* Queen Elizabeth
- *Rosa* Remembrance
- *Rosa* Sexy Rexy
- *Rosa* Sunset Boulevard
- *Rosa* Tall Story
- *Rosa* The Times Rose
- *Rosa* Trumpeter

### Extending flowering

Deadhead repeat-flowering roses throughout the summer to encourage them to bloom for a longer period. By removing the flowers, you prevent the plant from using its energy to form seed and stimulate it to produce more flowers instead. The easiest way to do this, and the way now practiced in many large gardens, is to bend the stem just below the old flower, as shown, until it snaps off. The plant will soon start forming new flower buds. Alternatively, use pruners to remove the flower and about 6 in (15 cm) of growth. The plant will then form more flower buds, but it normally takes longer than the "snapping off" method.

# Shearing lavender

Lavender (*Lavandula*) is a beautiful, aromatic shrub that can be grown on its own or as a low-growing, colorful hedge. To maintain a good shape, it is best sheared twice a year.



## Tip for success

After flowering, remove all the old flowerheads with pruners. This stops the plant from putting all its energy into making seed.

1 To keep your lavender plants young, bushy, and healthy, cut them back in late winter or early spring using clean, sharp hedge shears.

2 Shear the lavender as close as possible without cutting into the old wood. This is very important because the old wood does not regenerate, which means that if you cut into it, no new shoots will grow from the stems.

3 Here, you can see how the lavender has been cut just above where the new green shoots meet the old, brown wood. Shear to this point, and work systematically along and around the hedge, keeping it as level as possible.

4 This form of pruning encourages the lavender to become very bushy, and to produce a greater volume of flowers. The hedge then needs to be pruned again as the flowers fade in summer (*see Tip for success, opposite*).

# How to prune wall shrubs

*Euonymus fortunei* cultivars are vigorous plants that will grow even in poor soil. They often form rounded shrubs, but will also grow vertically, the variegated forms brightening walls and fences. Prune plants in late spring.

1 As with all variegated plants, it is important to remove any growths that are showing signs of reversion, where stems of all-green leaves appear. Cut these back to variegated foliage using pruners as soon as possible.

2 Using pruners, cut back to a suitable length any very long growths that are hanging away from the wall and causing the plant to lose its neat shape.

3 To keep it neat and bushy, trim over the whole plant with hedging shears. Keep one eye on the overall shape to ensure that you trim it as evenly as possible.

4 Remove any growths that are growing toward or into gutters or over doors and windows. When you are finished, the plant should resemble a closely clipped hedge growing against its supporting wall or fence.

*Garrya elliptica* is a useful evergreen shrub that produces long, pendulous catkins in the winter. It prefers to grow against the shelter of a wall for support and protection, and is best pruned in the spring, as the catkins are fading.

1 Any plant occasionally needs a trim to stop it from growing too tall or wide. For a shrub trained against a wall, trimming also prevents it from becoming too heavy and pulling or falling away from its support.

2 Start by pruning the longest horizontal branches to reduce the width of the plant. Always make the cuts above a leaf bud or stem shoot to encourage new, fuller growth during the coming year.

3 Once you have trimmed the horizontal branches, start pruning the tall, vertical stems. Cut them back to a height that is appropriate for the position of the plant.

4 If the plant is pruned carefully, it should still retain its natural shape afterward. The new growths that appear as a result of pruning will produce a good show of catkins the following winter.

# How to prune a mahonia

When evergreens such as this mahonia have outgrown their allotted space, they can be pruned back severely from midwinter to early spring, after flowering has finished.

## Tip for success

To keep plants short and bushy and to encourage greater flower production, remove flowerheads immediately after flowering.

1 Prune back tall stems, removing a little at a time, rather than cutting back the whole growth at once. At this stage, cut the stems to about 2 ft (60 cm) high, keeping in mind the plant's balanced shape as you prune.

2 Once you have cut back the tall growths, look to see where you can make your final pruning cuts. At the same time, remove any damaged, diseased, or crossing stems, and cut out any old growths to leave 5 or 6 strong stems.

3 Cut back the remaining young healthy stems so that they are 12–16 in (30–40 cm) above the ground. If possible, ensure that all the cuts you make are slightly sloping to encourage the rain to run off.

4 Later in the year, a mass of young shoots will grow from these shortened stems. The plant may not flower until two years after a severe pruning like this. Thereafter, to keep it bushy, follow the Tip for success (*see facing page*).

# Pruning a holly bush

A well-shaped holly (*Ilex*) can provide a wonderful structural focal point in the garden year-round. To maintain their shape, it is best to prune holly bushes in early spring.

## Holly hedge

Holly has thick, chunky growth, so holly hedges are best trimmed in late summer using a gas or electric hedge cutter.

1 To ensure that this young holly remains an attractive feature in the garden, it needs to be pruned annually, first to form a conical shape, and then to retain it.

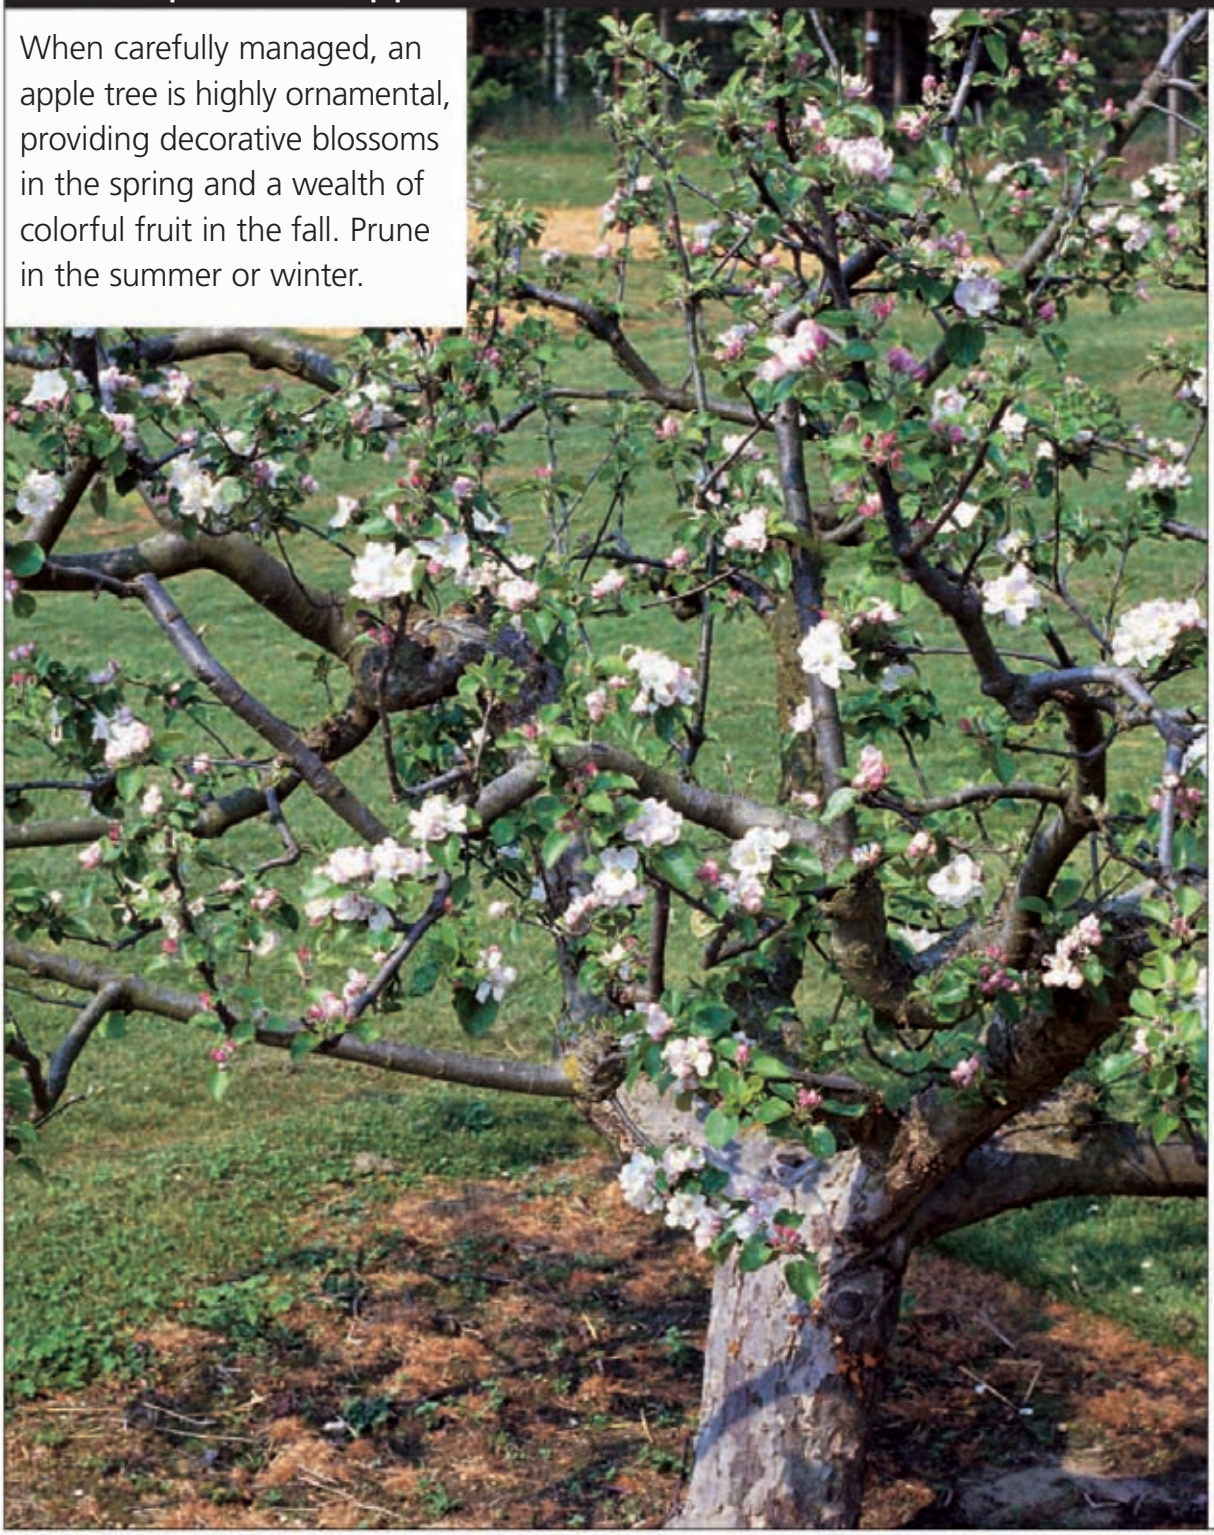
2 Remove some of the lower branches to create space under the bush and a short, clear stem. This is known as "lifting the skirt" and produces a bolder appearance.

3 If two branches are growing closely together at the top of the plant and causing it to lose its conical shape, cut the weaker one—or the stem that is least vertical—above a shoot that is growing in line with the conical outline.

4 Work all around the bush, trimming back any branches that are too long, until you have a conical shape that is symmetrical and pleasing to the eye.

## How to prune an apple tree

When carefully managed, an apple tree is highly ornamental, providing decorative blossoms in the spring and a wealth of colorful fruit in the fall. Prune in the summer or winter.



1 Start by removing any branches that are crowding the center of the tree. This will allow air to circulate, which reduces the risk of fungal infections during the summer. Also remove any dead, diseased, or damaged branches.

2 Cut the branches back to the collar (*see pp.170–171*). Make clean cuts with a sharp saw to reduce the risk of infection entering the wounds. Don't prune too hard, as it stimulates leafy growth at the expense of flowers and fruit.

3 Only reduce the height of the tree yourself if you can reach the top easily. Cut back any long branches by a half to one-third, or to a suitable side branch that, if possible, faces outward, to prevent crossing branches.

4 When pruning back to a side branch, make an undercut first, and saw halfway through the stem. Then make the final cut from above, sloping away from the side branch, to meet the undercut. This prevents the branch from tearing.

## How to prune an apple tree *continued*

5 The sloping cut you make after removing a branch (*above*) allows moisture and rainfall to drain off the cut surface, reducing the risk of rotting. The remaining side branch should also point outward.

6 Shorten any long, thin, whippy growths by cutting them back to short branches or spurs with a pair of pruning shears. This encourages flower bud formation from these branches.

7 Where pruning cuts have been made in previous years, remove any short, weak, or crowded stems growing around the wound. These are of no use to the tree and divert energy from the main branches and flower stems.

8 Remove all branches that are crossing or are starting to grow from the outside of the tree into the center. This helps to prevent branches from rubbing against each other in the future, thereby reducing the risk of disease.

9 Continue to work around the tree, removing unwanted branches and taking care to make clean cuts. Step back from the tree to ensure that you have created a balanced, simple framework, with an uncongested center.

# How to prune wisteria

Wisterias are beautiful plants for training up house walls and other structures. Prune these large, vigorous climbers twice a year, once in summer to keep the plant in check, and again in winter to help stimulate flowering.

## Summer pruning

1 Wisterias are vigorous plants, and during the summer after they have flowered, the plants produce very long tendril-like shoots that can block house windows or paths, or swamp their supporting structures.

2 To keep your wisteria tidy, reduce these shoots by two-thirds after the flowers have faded. This process may have to be repeated several times during the summer months as the plant continues to grow.

## Winter pruning

1 In late winter, when the leaves have dropped, you will be able to see the effects of your summer pruning. The pruned stems will have developed new growth, which will look lighter in color than older wood.

2 Spur prune (*see pp.172–173*) all the stems that you pruned in the summer back to two or three healthy buds. These buds will then swell to become flower buds in spring.

3 Also remove any stems that are growing into the eaves of the house, under shingles, or around drain pipes or down spouts. If left, they could cause damage to the house structure.

4 Ensure that all stems are tied to sturdy wires on the house or plant supports, as wisteria is not self-clinging. The plant will look quite bare, but the buds will develop into a wall of scented flowers in late spring or early summer.

# Cutting back clematis

Admired for their beautiful flowers, clematis can put on an almost year-round show. They are divided into three groups, each with different pruning needs, so work out which one yours belongs to and follow these guidelines.

## Group 1

Group 1 clematis are vigorous plants, and include *C. montana*, *C. alpina,* and *C. armandii*. Flowering in late spring on the previous year's growth, they require very little pruning. Prune lightly immediately after they have flowered to contain their size, and remove any dead, diseased, or damaged growth.

*Clematis montana* (Group 1)

*Clematis* "Frances Rivis" (Group 1)

## Group 2

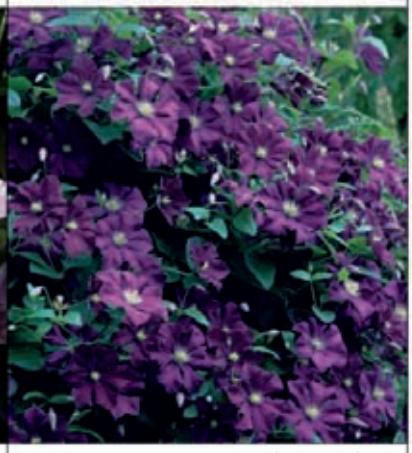
This group of early summer-flowering clematis have large flowers that are produced from the previous year's growth. Many will also produce a second flush of flowers in late summer. Group 2 clematis require a light prune in early spring. Prune back stems to a pair of healthy buds.

*Clematis* "Nelly Moser" (Group 2)

*Clematis* "H.E.Young" (Group 2)

## Group 3

Group 3 clematis include the small-flowered viticella and texensis types, *C. tangutica* and its cultivars, and some large-flowered hybrids. They bloom from midsummer to fall on new season's growth and require hard pruning in early spring, or you can prune them more lightly.



*Clematis* "Etoile Violette" (Group 3)

*Clematis tangutica* (Group 3)

## Pruning after planting

Help all groups of clematis to get established by pruning them after planting in spring, or in their first year immediately after flowering. Reduce the plant's height by one-half, ensuring that you prune above a pair of healthy buds. This encourages the plant to produce growths from all the buds on the stem below the pruning cut, which will ultimately give you a much stronger plant. It also encourages root production, helping to develop strong, healthy growth. Take care when handling any clematis as the shoots can be very brittle.

## Pruning Group 1

Immediately after flowering, give Group 1 clematis a light trim to help contain the size of the plant and to keep it looking tidy. Prune strong, leggy new season's growths, cutting above a pair of healthy buds. This will also help to show off the plant's attractive fluffy seedheads, but don't prune too hard or you will remove them. If a plant becomes too large, occasionally prune all stems back to 6 in (15 cm) from the ground in early spring. Montanas may not recover from this treatment, so only carry out drastic pruning if you have no choice.

## Pruning Group 2

Prune Group 2 clematis in early spring when the buds are already in growth and new stems are visible. Work from the top of the plant, pruning each stem back to the first pair of healthy buds or growths. Remove any dead, diseased, or damaged wood. New growths will appear along the pruned stems, and these produce the flowers in early summer. If the plant has outgrown its site, hard-prune all stems to 6 in (15 cm) from the ground in early spring. It may not flower during the coming summer, or it may bloom later in the season.

Prune above a pair of healthy buds

Cut away excess growth in spring

Prune lightly back to new growth

New growth soon emerges

Pruning helps to show off seedheads

Buds open below the pruning cuts

# How to prune a Group 3 clematis

The late-flowering *Clematis* x *jouiniana* is extremely vigorous, and is suitable for clothing large supports or growing through substantial shrubs or small trees. As it belongs to pruning Group 3, it requires hard pruning in early spring.

1 This clematis has been grown over a large pyramid support made from birch twigs. Start pruning by removing all the loose growths that are covering the support.

2 Once all the stems have been removed from the support, you will have better access to the base of the plant. Prune back all long growths to give a manageable clump of short stems before making your final cuts.

3 Prune the growths hard back to one or two buds from the ground, as shown. Always make straight cuts just above a pair of healthy buds to reduce the risk of dieback.

4 You will be left with a mound of growths about 6 in (15 cm) high. To encourage healthy growth, add a little fertilizer and mulch. The plant will then grow 6–10 ft (2–3 m) and be covered in flowers during late summer.

Lightly pruning late-flowering Group 3 clematis, such as this *Clematis tangutica*, encourages the plant to flower earlier.

Follow these simple steps to create a cascade of beautiful yellow nodding flowers throughout the summer.

1 In early spring and starting at the top of the plant, lightly prune back the main stems to fit the shape of the support. As with any pruning, also remove dead, damaged, or diseased stems as you work.

2 Then lightly prune the side stems back to the plant support. This will maintain the shape of the plant and encourage strong new growths that will flower in the summer. Make sure all cuts are made above two buds.

3 If there are strong young growths coming from the base of the plant, tie them into the rest of the clematis so that they will not blow around in the wind and get damaged—clematis stems are brittle and easily broken.

4 When you have finished, the clematis should look as if it has had a light haircut, since you have just trimmed it back to the shape of the supporting structure.

# Cutting back honeysuckle and ivy

Climbing honeysuckles (*Lonicera*) are grown for their beautifully scented flowers. Allow them to scramble over shrubs and trees in the garden, or encourage them to climb up supports, such as fences or trellises.

Climbing honeysuckles are easy to grow, and produce masses of sweetly scented blooms in the summer. As they age, plants can become woody at the base, and look untidy and overgrown. Keep them in check and flowering prolifically by pruning regularly.

1 In spring, contain the size of a honeysuckle by removing long, straggly growths and reducing the overall height of the plant by 12–20 in (30–50 cm).

2 Remove old, dead, damaged, or diseased stems. If your plant is overgrown, cut all the stems back to about 6 in (15 cm) from the ground. New shoots will soon appear from the base, but you may lose the flowers that year.

3 Unless you gave the plant a hard prune, by late summer it will produce an even covering of flowers. If the plant has put on a lot of growth and is looking untidy, trim it again immediately after flowering has finished.

Ivies are versatile evergreen climbers that will grow in sun or shade, and adhere to almost any support or surface. In late spring or early summer, prune these vigorous plants to contain their spread and keep stems from clogging gutters.

1 The aim of pruning here is to reduce the plant's spread over the fence and to remove it from the tree trunk in front. Ivy can collect a lot of dust and dirt, so wear a dust mask when pruning if this affects you.

2 Working from the top of the fence panel, pull away long lengths of ivy. When you are happy with the amount removed, cut off the stems with pruning shears. Also cut away any ivy growing on tree trunks or other plants.

3 Remove ivy growing up walls and into gutters. When removing ivy from walls, you will reveal marks left by the roots, which help the ivy to cling to the surface. Use a stiff brush to remove the root residue.

4 The ivy has been cut back from the top of the fence by about 18 in (45 cm) to allow room for regrowth. It has also been removed from the tree trunk, resulting in a less cluttered and lighter part of the garden.

# How to prune a rose on a tripod

Climbing roses, such as this *R.* "White Cockade," can be trained over a wooden tripod to create a lovely focal point in a small space. Prune the rose in the fall or early spring.

## Before pruning

The plant is a mass of stems, some of which are old and must be removed, while younger stems need to be tied in.

1 Start by removing the rose stems from the tripod support. Cut all the ties that are holding the rose to the support, and then carefully unwind the stems, working down from the top of the plant.

2 Cut out any dead, damaged, or diseased wood. Then remove about one in three of the oldest stems by pruning them close to the base of the plant. Leave enough stems unpruned to cover the tripod.

3 With the unpruned older stems that you left to cover the tripod, spur-prune the previous season's flowering stems (*see pp.172–173*), and tie them into the tripod. These spurs will produce flowering stems in the coming summer.

4 Tie back the remaining young flexible stems using garden twine. To give the best coverage over the tripod, tie some in a clockwise and others in a counterclockwise direction.

# Pruning rambling and climbing roses

Ensure a mass of flowers each year by pruning rambling and climbing roses during the fall while their stems are still quite flexible. If you don't have time in the fall, these roses can also be pruned in late winter or early spring.

1 Remove one in three of the oldest flowering stems. These growths will be quite thick and should be cut back to almost ground level using a pruning saw or loppers.

2 Use sharp pruning shears to spur-prune the previous summer's flowering stems back to two or three healthy buds (*see pp.172–173*). These will then produce flowering stems during the coming summer months.

3 Use garden twine or special rose ties to tie in all the stems. Bending flexible stems over and tying them onto horizontal supports or wires encourages the production of more flowering growths.

## Summer maintenance

Do not attempt to prune a rambling rose in the summer. Tie in and support the long, strong new growths that have been produced, so that they are not damaged or broken. These are the stems that you will be cutting back when pruning and training in the fall.

This climbing rose has been carefully pruned and trained along horizontal wires that have been attached to the wall with vine eyes. Place galvanized wire at about 12-in (30-cm) intervals up the wall before planting your rose.

1 Cut all the ties that are holding the rose to the wires and pull the stems away from the wall. Remove one in three of the oldest flowering stems. Do not remove any of the strong new growths produced from the base of the plant.

2 Spur-prune last season's flowering stems back to two or three healthy buds (*see pp.172–173*) to encourage them to produce more flowering stems in the months ahead.

3 Tie all the remaining growths back onto the wires, and try to cover as much of the wall as possible. You may find some of the stems cross over each other, but this won't be a problem as long as they don't rub.

4 Step back from time to time to ensure that you have tied the stems in a fan shape over the wall. By the time summer arrives, the plant will have produced more stems covered in leaves and flowers and the wall will be hidden.

# Choosing a site

Growing vegetables in ideal conditions is not always possible, particularly if you have limited space, but it pays to find a sunny spot that is sheltered from the wind and easily accessible for watering and weeding.

## Sheltered or sunny walls

A wall that faces the sun provides plants with protection from the wind and reflects the sun's heat back onto your crops during the day. It will also absorb heat and release it at night when the air temperature falls. A sheltered microclimate is ideal for growing heat-loving vegetables, such as tomatoes, eggplants, and peppers, so if you have one in your garden, make the most of it. Improve the soil, create a raised bed, or position pots at the base of the wall. Remember to keep plants well watered.

**Tips for sunny walls**

- Add supports, such as wire mesh, to the wall to secure tall and scrambling plants as they grow.
- Take advantage of a sunny wall as the perfect backdrop for tomatoes in a growing bag.
- Be adventurous and try growing more unusual crops, such as sweet corn and chili peppers.

A greater range of vegetables can be grown by a sunny wall.

## Small vegetable beds

Make the most of a small space by planning your crops carefully and squeezing as much variety into the plot as possible. Many vegetables are attractive plants in their own right, but add extra color to the beds by including some flowers, too, which will not only look good but also help attract pollinating insects. Planting vegetables close together also means that there is little bare soil on which weeds can establish, helping to minimize maintenance, but crop yields may be slightly reduced.

**Tips for small vegetable beds**

- Densely planted vegetables need rich soil, so work in plenty of organic matter in fall.
- Choose vegetable varieties with interesting colors and forms to add drama to your beds.
- Be wary of planting too close to tall hedges, which cast shade and take moisture from the soil.

Rows of vegetables packed tightly together will suppress weeds.

## Growing under cover

Protecting crops from cold and wet weather in a greenhouse, cold frame, or under cloches gives them a head start in spring, extends the growing season into fall, and allows a range of tender vegetables to be grown that may not perform well outdoors. Fitting large structures into a small garden can be difficult, so consider whether you have a suitable site before buying costly equipment. Site greenhouses and frames in full sun, away from overhanging trees, but sheltered from the wind as much as possible. Plants under cover rely on the gardener to provide adequate water and temperature control, which can amount to a lot of work, so make sure you have the time.

**Tips for growing under cover**

- Control greenhouse ventilation to regulate temperatures and remove damp air that can encourage disease. Automatic ventilation is a good investment.
- Use cold frames and mobile cloches for raising seedlings and protecting young plants.
- Where there is no space outdoors, try sowing seeds and growing heat-loving crops on a sunny windowsill.
- Install a water supply, such as a rain barrel, next to the greenhouse to make life easier.

It is crucial to choose a site in full sun for your greenhouse.

## Container growing

Filling pots, troughs, and window boxes with a range of vegetables is one of the best ways for those with little or even no garden to harvest their own homegrown produce. Tomatoes, salads, dwarf beans, herbs, and some root vegetables are just a few of the crops that will thrive in containers and can make attractive displays on patios, steps, and windowsills. Containers filled with good-quality potting mix are also useful in gardens with very poor soil or where soil-borne pests and diseases make vegetable growing difficult. However, containers can be expensive to buy and fill with potting mix, and without regular watering and fertilizing, plants will not perform well, so consider the practicalities before you begin.

**Tips for container growing**

- Keep costs down and be creative by making your own pots from galvanized metal bins or plastic containers.
- Good drainage is vital to prevent soil from becoming waterlogged, so be sure pots have holes in their bases.
- Choose large pots, as they hold more soil, take longer to dry out, and suit many vegetables well.
- Look for vegetable varieties suited to container growing, such as short, round carrots.

Colorful crops, like this chard, are easy to grow in pots.

# Making compost

Every gardener should find space for a compost pile or bin, as it turns garden and kitchen waste into a valuable source of organic matter to dig into soil or use as a mulch.

**The final product** Compost should be dark brown with a crumbly texture and pleasant, soil-like smell. The decomposition of bulky organic materials requires oxygen, moisture, and the right balance of carbon- and nitrogen-rich waste (*opposite*), which means that careful management is necessary. However, a successful compost pile is easy to achieve.

**Different compost bin designs** Your first task is to find a compost bin that suits the size of your garden and the amount of waste to be broken down. It is best to have two bins, to allow the contents of one to be aerated by turning it into a second bin, which means that a new pile can be started in the first. The type of bin you choose depends on appearance, space, and cost considerations, but ensure that it has a loose-fitting cover to prevent waterlogging. Place your bin on bare soil, add compostable material, and let nature do the rest.

Wooden bins look good and can be bought or homemade. Choose a design with removable front slats for easy turning.

Plastic bins are relatively cheap and simple to install, but their design means that turning the contents can be tricky.

Bins constructed from wire mesh are particularly suitable for composting fallen leaves to make leafmold.

**What goes on the pile?** Almost all garden and kitchen waste can be composted, except for diseased material, perennial weeds, and meat and cooked waste, which attracts vermin. Nitrogen-rich (green) waste aids decomposition, but this must be balanced with carbon-rich (brown) waste to open up the structure of the pile and allow air to circulate. Aim to add a 50:50 mix of green and brown waste to your pile during the year.

### What to add

- Carbon-rich woody prunings and hedge trimmings (which usually need to be shredded), plant stems, fall leaves, shredded newspaper and cardboard.
- Nitrogen-rich grass cuttings, herbaceous plant material, weeds, vegetable plants, fruit and vegetable peels, tea bags, coffee grounds.

Carbon-rich brown material adds bulk.

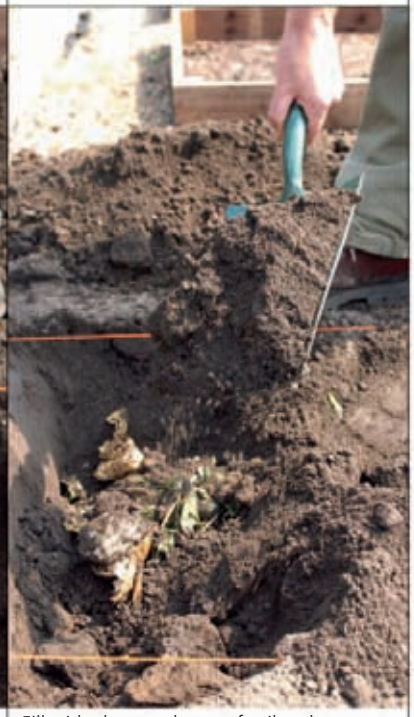
Chop up woody material before adding.

### Making a compost trench

Kitchen waste, such as fruit and vegetable peels, tea bags, and eggshells can also be composted in a long trench. The trench is best made during the fall, when large areas of soil are often bare and the waste has time to break down before planting begins in spring. Vigorous plants, such as runner beans and squashes, respond particularly well to the high nutrient levels provided by kitchen leftovers.

Dig a trench about 12 in (30 cm) wide to one spade's depth and fill it with alternate layers of waste and soil. Then add a layer of soil on top. Allow at least two months before planting over the trench. As with any composting method, do not include meat or cooked waste because it may attract vermin.

Scatter waste on the bottom of the trench.



Fill with alternate layers of soil and waste.

# Water-wise gardening

Droughts and water metering can cause problems during hot, dry summers, but the solution is to know how to use resources efficiently and to store your own supplies.

**Keeping plants healthy** Plants in dry soil are susceptible to disease and yield less, so it pays to keep soil moist. Watering thoroughly so the moisture penetrates deep into the soil is better than wetting the surface daily. Water in the evening or early morning to minimize evaporation.

**Storing rainwater** Water can be collected from the roofs of houses, garages, sheds, and greenhouses, and stored in rain barrels that have spigots at their bases. These supplies of rainwater are a valuable alternative to city water or well water, although during hot summer months, rainfall rarely keeps up with demand.

Rain barrels are often easier to install in a convenient part of the garden than running a hose to the area. Make sure that you set your rain barrel on a stack of bricks, slabs, or a specially made base, to allow a watering can to fit under the spigot. Although many gardeners dislike the appearance of plastic barrels, they are easy to disguise with ornamental planting, such as grasses and bamboo (*right*), or tall rows of runner beans.

**Using gray water** Water that has already been used in the home is usually suitable for watering plants in the garden. Normal household soaps and detergents do not damage plants, but avoid bleaches and strong disinfectants. Allow hot water to cool before applying it to the soil.

**Water the roots** Pour water around the stem base, beneath the plant's foliage, so that it is absorbed into the soil around the roots where it is needed. The shade of the foliage also helps to prevent evaporation, and neighboring weeds are not inadvertently watered, too.

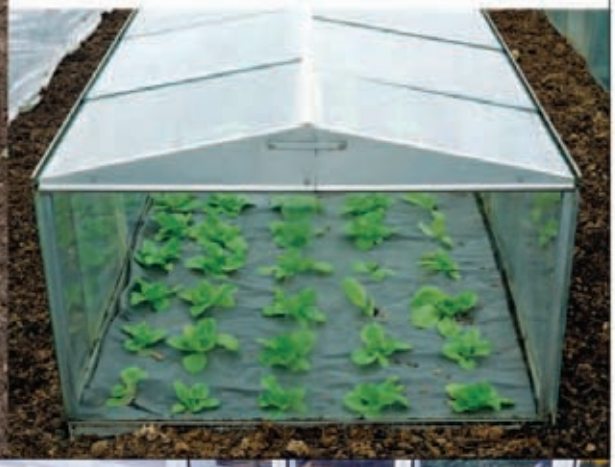
# Cloches and cold frames

Protect crops from pests and bring on their growth in cold weather by covering them with cloches or growing them in permanent cold frames.

**Plastic bottle cloches** Many plants benefit from protection in cool spring and fall weather. Commercial cloches can be expensive; large, clear plastic bottles, cut in half and placed over plants, are an effective alternative.

**Corrugated plastic cloches** Whole rows of plants can be covered using long, low tunnel cloches, which are left open at the ends for thorough ventilation or closed off when greater protection is required. No rain will reach cloched plants, so remember to water them as necessary.

**Rigid plastic cloches** These large cloches are ideal for protecting blocks of young plants or more substantial crops, such as zucchini or early potatoes. The warm, dry atmosphere is also perfect for drying onion crops after harvest. Anchor these light structures to the ground.



**Cold frames** Usually permanent structures of brick with framed glass "lights," cold frames are useful for hardening off young plants and extending the productive season of crops such as salads and zucchini. Constructed in a sheltered, sunny spot, they are a good alternative to a greenhouse in a small garden, with the angled glass allowing water to run off and the maximum amount of light to reach the plants. A frame with a hard base is suited to acclimatizing pot-grown plants to outdoor temperatures, while a bed of improved soil allows crops to be grown in the frame. Prop the lights open during the day to provide ventilation, and keep plants inside well watered.

# Root crops

## Cultivation tips

**How to grow** Easy to grow, most root crops simply need to be sown outdoors and kept free of weeds and pests to do well. With carefully selected varieties and successional sowing, you can harvest root crops all year.

**Site and soil** Many root crops like well-drained, slightly acidic soil that holds organic matter, with some nutrients dug in. Potatoes, however, crop best on recently manured soil. Brassica root crops may succumb to clubroot in acidic soil that has not been limed. Stony soil may cause malformation of long-rooted crops.

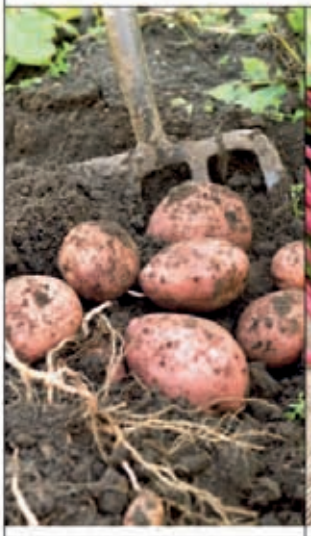
**Sowing** Most root crops can be grown from seed outdoors from early spring. Sow into drills at a depth of about ¾ in (2 cm) Potatoes need a depth of 4 in (10 cm). Cover with soil and water in. Sow carrots, beets, turnips and radishes every few weeks for a continuous supply.

**Care and potential problems** Thin seedlings out, leaving strong plants to grow on at the correct spacing. Keep the surrounding soil weed-free and moist, watering in dry spells. Protect potato plants from frost and cover their lower stems and leaves with soil as they grow.

**Roots in pots** Carrots, beets, and radishes all grow happily in containers at least 10 in (25 cm) wide and deep—larger pots are needed for potatoes—as long as they are kept well watered. This is a good way to start the earliest crops under cover.

**Growing potatoes through black plastic** If earthing up potatoes sounds like too much effort, try planting your crop through holes cut in a layer of thick black plastic—push the edges into the soil to secure the plastic in place. This keeps out the light and helps warm the soil for a fast-maturing crop.

## Crops to choose



**Potato** Early varieties suit small gardens since they are harvested by midsummer, whereas maincrops tie up the soil until mid-fall.

**Beet** Not all beets are red, so you can choose unusually colored varieties and opt for bolt-resistant types for early sowings.

**Parsnip** These roots will stand in the soil through winter with a covering of straw, but seeds need to be sown the previous spring.

**Radish** Sow radishes successionally for crops over a long season. Exotic hardy winter radishes can also be sown in summer.

# Brassicas

## Cultivation tips

**How to grow** Encompassing many of the hardiest winter crops, including cabbages and Brussels sprouts, this group also includes many summer favorites and Asian greens.

**Site and soil** Moist, well-drained, fertile soil suits most brassicas, so it is best to work in plenty of organic matter well in advance of planting. Lime should be added to soil with a pH lower than 6.8 to prevent clubroot. Brassicas prefer full sun, but will tolerate partial shade, while taller plants, such as Brussels sprouts, need to be staked on windy sites.

**Sowing** Most brassicas are best sown into an outdoor nursery bed under cover in spring and transplanted into their final positions as young plants. However, sow summer sowings of calabrese and kohlrabi directly into seedbeds in their final positions.

**Care and potential problems** Brassicas like cool weather and tend to bolt during hot, dry spells. Water transplants daily and mature plants once a week in dry weather. Cover plants with floating row cover to prevent butterflies from laying eggs on them. Slugs, aphids, and whiteflies all enjoy brassicas. Take measures to avoid clubroot.

**Thwarting insect pests** To keep cabbage maggots and cutworms from destroying young plants, buy protective collars, or make your own. Cut 6-in (15-cm) squares of thick paper, cut a slit, and fit.

**Coming back for seconds** Broccoli and calabrese continue to produce secondary spears after the central one is cut, and frequent harvesting encourages even more. When harvesting summer cabbages, leave 2-in (5-cm) stumps and cut a cross ½ in (1 cm) deep in the top. This will encourage a second crop to develop.

## Crops to choose

**Cauliflower** Best in rich, heavy soils with plenty of manure. Snap outer leaves over each curd to protect them from sun and frost.

**Kale** Hardy and tolerant of poor soil, kale is easy to grow. Colorful, textured varieties brighten up the winter garden.

**Brussels sprouts** Harvest this classic winter vegetable from the base of the stem upward, by snapping off each sprout by hand.

**Kohlrabi** Eat the swollen stems of these fast-growing exotics in salads or stir-fries. Harvest when no larger than a tennis ball.

# Legumes

Pea and bean crops require less fertilizer than other vegetables because their roots are home to bacteria that take nitrogen from the air and fix it in the soil. Leave the nutrient-rich roots to break down in the soil after harvest.

Sugar snap peas ready for harvesting.

## How to grow

**Site and soil** These climbing plants do best in full sun in fertile, slightly alkaline soil, improved with plenty of organic matter. Since they are susceptible to similar pests and diseases, practice crop rotation (*see p.270*). Fava beans prefer clay soil, while other peas and beans do best in lighter soil. Provide shelter from strong winds.

**Sowing and planting out** All legume seeds need warm soil in which to germinate, so wait until mid-spring to sow outdoors or start them off under cloches or in pots indoors. Successional sowings help to ensure a steady supply of produce. Erect appropriate supports before sowing or planting out to avoid damaging young plants.

**Care and potential problems** Beans are commonly grown up teepees or rows of canes held together with string; peas scramble up chicken wire supported by canes or twiggy sticks. Beans may need coaxing up and tying into their supports, while peas hold on with tendrils.

Keep plants well weeded, and mulch if possible. There is no need to water before flowering, unless plants are wilting. Begin watering generously when flowering starts, to encourage pods to set. For bushier plants, pinch out growing tips when plants reach the top of their supports.

Rodents love legume seeds, so sow indoors if this is a problem. Protect crops from pea moths with floating row cover. Infestations of aphids are also common.

**Harvest and storage** Peas and beans are at their tastiest when small and freshly picked, so harvest frequently; this also encourages greater yields. Eating quality deteriorates quickly, even when crops are refrigerated, so either use right away or freeze any excess as soon after harvest as possible. Cranberry beans can be left on the plant to mature, then dried and stored in a cool, dark place.

### Sowing depths and spacing

| CROP | SOWING DEPTH | SPACING | |
|---|---|---|---|
| | | Plants | Rows |
| Fava beans | 3 in (8 cm) | 10 in (25 cm) | 12 in (30 cm) |
| French beans, dwarf | 2 in (5 cm) | 4 in (10 cm) | 18 in (45 cm) |
| climbing | 2 in (5 cm) | 6 in (15 cm) | 18 in (45 cm) |
| Runner beans | 2 in (5 cm) | 6 in (15 cm) | 18 in (45 cm) |
| Peas | 1½ in (4 cm) | 4 in (10 cm) | 18–24 in (45–60 cm) |

## Cultivation tips

**Discouraging black aphids on fava beans** Black aphids are fond of the young, sappy growth at the tips of fava bean plants. Deter them by pinching out the tips when plants have plenty of flowers and the first pods have set.

**Supporting runner beans** Climbing French and runner beans need the support of sturdy canes, ideally at least 7 ft (2.2 m) tall, to hold up their lush growth. Teepees of six or eight canes tied at the top are easy to construct.

## Crops to choose

**Colorful peas** With violet flowers and pods, the snow pea 'Ezethas Krombek Blauwschok' adds color to the productive garden.

**Fava beans** Rarely available fresh in stores, these delicious beans are easy to grow and can be sown in fall for a welcome late spring crop.

**French beans** Dwarf varieties of this heavy-cropping legume suit the small garden very well. They thrive in pots to yield plenty of gourmet beans.

**Cranberry beans** Grown in the same way as a climbing French bean, this Italian variety has pink-flecked pods. Eat the beans fresh or use them dried.

# Alliums

## Cultivation tips

**How to grow** Alliums include onions, leeks, and garlic. All are strongly flavored and simple to grow in free-draining soil.

**Site and soil** A sunny, open site with fertile, well-drained soil is ideal for members of the onion family because they are prone to fungal diseases in damp conditions. Treat soil with a pH of less than 6.5 with lime, and don't grow alliums in the same place every year. Manure the ground a few months in advance to stop too much soft growth.

**Sowing and planting out** All alliums, except garlic, can be grown from seed. Sow in modules in early spring under glass for early crops, or outdoors for later crops. Harden off seedlings and plant out at the desired spacing, or thin direct-sown rows. The final spacing dictates the harvest size of the bulbs. Transplant leek seedlings when they are pencil-size. Drop them into holes 6 in (15 cm) deep and the width of a spade shaft. Water well, but do not backfill with soil. Succession-sow green onions. Onions and shallots can also be planted as sets (and garlic as cloves). Place sets 4 in (10 cm) apart in shallow drills.

**Care and potential problems** Water onions and shallots in very dry weather. Leeks respond well to regular watering and a mulch. All alliums are susceptible to fungal diseases, including onion white rot, downy mildew, and fusarium. Maintain good air flow around the plants and remove any infected material.

**Harvest and storage** Harvest leeks and green onions when green, but allow the leaves of onions, shallots, and garlic to yellow and die down before lifting them. Store onions, shallots, and garlic on a wire rack until the leaves rustle; then hang them in a cool, dry place.

## Crops to choose

**Onions** Small or heat-treated onion sets are less likely to bolt and are a good choice for novices wanting a trouble-free crop.

**Shallots** A single shallot set will divide to produce a crop of several small, sweet bulbs, which are expensive in stores.

**Garlic** Do not plant supermarket cloves; you will achieve better yields using virus-free stock of cooler-climate varieties.

**Green onions** A quick, easy onion, ideal for the gaps between slower-growing crops. Try one of the unusual red varieties.

# Cucurbits

## Cultivation tips

**How to grow** Vigorous and high-yielding, these plants, which include pumpkins, zucchini, and cucumbers, are great fun to grow. Trailing varieties look good scrambling up a fence or over an arch. Some cucurbits may need hand pollination: female flowers have mini-fruit behind them, while male flowers grow on a thin stem. Remove male cucumber flowers in the greenhouse to prevent pollination and deformed, bitter fruits.

**Site and soil** Plants in the pumpkin family come from hot climates and thrive on well-drained soil enriched with organic matter. Once established, their growth can be rapid and extensive, so leave them enough space. Cucumbers do well in pots or growing bags.

**Sowing and planting out** These tender plants cannot tolerate frost and will not grow in the cold. Sow seeds indoors, in biodegradable pots to prevent root disturbance, and plant seedlings out when the weather improves. Harden seedlings off before planting out after the last frost.

**Care and potential problems** Cucurbits require lots of watering. Cucumbers and squashes often benefit from sturdy supports: cane teepees, fan trellises, and wires in the greenhouse are all effective. Cucurbits are mostly pollinated by insects. Powdery mildew may occur and cucumber mosaic virus can cause deformed fruits. Red spider mite and whiteflies can also be a problem.

**Harvest and storage** Leave pumpkins, and squashes on the plant until they have a hard skin and cracked stem, and for longer, if possible, if they are to be stored. Cut with a long stem and cure in a warm room for several days, before storing somewhere cool and dry.

## Crops to choose

**Zucchini** Easy to grow and productive, zucchini usually has a bush, rather than trailing, habit, and suits small gardens.

**Cucumber** The smooth-skinned greenhouse types of cucumbers are more difficult to grow than outdoor ridge varieties.

**Summer squash** Strangely shaped, soft-skinned squashes taste the same as zucchini and can be cooked in the same way.

**Pumpkin** A late summer bounty in the garden. Select varieties grown for flavor rather than size if they are for the kitchen.

# Fruiting vegetables

These sun-loving crops are a popular choice for patio containers and warm windowsills. There are varieties to suit every size of garden and all kinds of climate, and the right selection will yield delicious late summer crops.

## How to grow

**Site and soil** Provide a warm, sunny site, with light, fertile, well-drained soil for these tender crops. All, except sweet corn, will flourish in containers, in a greenhouse or by a sunny wall. Warm the soil by covering with cloches or clear plastic before planting.

**Sowing and planting out** Sow crops under cover, at 60°F (16°C) or warmer, in early spring. Where small numbers are required, sow seeds into individual pots of multipurpose potting mix, and cover with sifted potting mix. Keep growing seedlings in a well-lit place. Harden plants off in a cold frame or outside under floating row cover for a week before erecting supports and planting out in the final positions. Pots should be at least 10 in (25 cm) wide and deep. Sweet corn can be direct-sown outdoors in mild areas from mid-spring.

**Care and potential problems** Water well during flowering and when fruits are developing. Cordon tomatoes need tying into supports, and sideshoots that appear where leaves join the main stem should be pinched out. Pinch out the growing tips of eggplants and peppers to encourage compact growth. When fruits begin to set, apply a liquid fertilizer weekly. Aphids, red spider mites, and whiteflies are common on crops grown under cover, as is botrytis (gray mold). Tomatoes are susceptible to blight, potato cyst eelworm, and viruses. Sweet corn is a favorite with animal pests; mice eat seed in the soil, while birds, squirrels, and raccoons can ruin crops.

**Harvest and storage** Pick eggplants while the skin is glossy. Uproot outdoor tomatoes and peppers before the first frost and hang in a greenhouse to ripen the last fruits. Check sweet corn for maturity when the silks turn brown by piercing a kernel; white juice shows ripeness.

### Sowing depths and spacing

| CROP | SOWING DEPTH | SPACING | |
|---|---|---|---|
| | | Plants | Rows |
| Eggplants | ½ in (1 cm) | 18 in (45 cm) | 24 in (60 cm) |
| Peppers (sweet and hot) | ½ in (1 cm) | 18 in (45 cm) | 24 in (60 cm) |
| Tomatoes, bush | ¾ in (2 cm) | 24 in (60 cm) | 24 in (60 cm) |
| cordon | ¾ in (2 cm) | 18 in (45 cm) | 24 in (60 cm) |
| Sweet corn | 1½ in (4 cm) | 18 in (45 cm) | 18 in (45 cm) |

A truss of tomatoes, ripe for harvesting.

## Cultivation tips

**Watering tomatoes** The best way to water tomatoes is to insert a pot, or a plastic bottle cut in half, with holes in the base, into the soil next to each tomato plant and water into it. This delivers moisture directly to the deeper roots and reduces evaporation rates.

**Assisting sweet corn fertilization** Arrange plants in dense blocks where the pollen will be concentrated, to maximize the yield. These plants rely on the wind to disperse their pollen, and planting in this way encourages the best possible crop.

## Crops to choose

**Sweet corn** These plants look stately in flower beds, and the freshly picked cobs, cooked seconds after harvest, taste terrific.

**Sweet pepper** Easy to grow, the long, thin-walled varieties of grilling pepper look pretty on the plant and have good flavor.

**Eggplant** When pinched out to keep them bushy, eggplants make attractive plants for patio pots in warm areas.

**Chili pepper** Easy to grow, these fiery fruits only ripen reliably under cover. Try them on a windowsill and freeze any excess.

# Perennial and stem vegetables

Often disappointing when store-bought, these vegetables are a gourmet treat when freshly picked. They are easy to grow, and perennial types also suit the ornamental garden. The stem vegetables celery and celeriac are not perennials.

Apply fertilizer to asparagus in early spring.

## How to grow

**Site and soil** Choose a sunny, open site, with deep, free-draining soil, and fork in plenty of organic matter before planting. Celery thrives only in very rich, moist soil, so if your soil is poor, you may do better with celeriac.

**Sowing and planting out** Asparagus and globe artichokes are difficult to grow from seed, so many gardeners start in spring with asparagus crowns and young globe artichoke plants. To plant asparagus, dig a trench 8 in (20 cm) deep and at the bottom make a central ridge with soil; spread the crown's roots over the ridge and cover with soil so that just the tips are showing. Plant globe artichokes in rows, keeping the leaf rosette above the soil. Simply bury Jerusalem artichoke tubers in the soil. Sow celery and celeriac seed indoors from mid-spring and harden off when they have five to six leaves, before planting out. Water plants in well. Self-blanching celery is an easy choice for beginners.

**Care and potential problems** Jerusalem artichokes may need support. Water and mulch globe artichokes in dry weather. Mulch the asparagus bed with organic matter, and apply fertilizer in early spring and after harvesting. Cut down when growth yellows in fall. Water celery and celeriac weekly, and mulch with straw or compost. Globe artichokes may be attacked by black bean aphids, and Jerusalem types can be invasive, so keep them in check. Fungal rots may affect all crops in wet weather.

**Harvest and storage** Harvest celery plants whole before the first frost. Celeriac is hardy and best left in the ground until required. Cut asparagus spears about 2 in (5 cm) below the soil surface when they are about 6 in (15 cm) tall. Cut the heads of globe artichokes while still tight. Unearth Jerusalem artichokes as and when required.

### Sowing depths and spacing

| CROP | SOWING DEPTH | SPACING | |
|---|---|---|---|
| | | Plants | Rows |
| Celery | On surface | 10 in (25 cm) | 10 in (25 cm) |
| Celeriac | On surface | 12 in (30 cm) | 12 in (30 cm) |
| Asparagus | 1 in (2.5 cm) | 10 in (25 cm) | 12 in (30 cm) |
| Globe artichoke | n/a | 30 in (75 cm) | 36 in (90 cm) |
| Jerusalem artichoke | 4 in (10 cm) | 12 in (30 cm) | 12 in (30 cm) |

## Cultivation tips

**Earthing up celery** Trench celery is a traditional garden crop (*see left*). The stems are blanched by covering the stems with soil, known as "earthing up," to exclude light. Tie the stems together with string when the plant is 12 in (30 cm) tall, and pile soil around them to half their height. Repeat every three weeks until just the tops are showing in late fall.

**Mulching globe artichokes** Globe artichokes, particularly young plants and those growing in cold areas, can be damaged by frost, so protect them during the winter by earthing up around them and covering the plant with a 6-in- (15-cm-) thick mulch of straw, or a double layer of floating row cover.

**Harvesting young asparagus plants** Patience is a virtue when establishing an asparagus bed. Resist harvesting the spears for the first two years after planting, to allow the plants to gather strength for future years. Harvest for six weeks in late spring in the third year and for eight weeks in the years that follow.

## Crops to choose

**Celery** Self-blanching varieties are best grown close together in tight blocks or cold frames to produce tender, pale stems.

**Celeriac** This knobby vegetable tastes much better than it looks and is delicious roasted, mashed, or in soups.

**Globe artichoke** A tall, easy-to-grow decorative plant with silvery foliage. The mature flower buds are a real delicacy.

**Jerusalem artichoke** The tubers are usually cooked but can be eaten raw. Plants are tall and make a good windbreak.

# Salad and leafy vegetables and herbs

Everyone has room for a little pot of herbs or a window box of cut-and-come-again salad leaves. They are so easy to grow that you'll wonder how you managed before without all those fresh flavors on your doorstep.

## How to grow

**Site and soil** Salad crops, chard, and many herbs tolerate most soils, except waterlogged, and don't demand a lot of soil preparation. However, spinach and Asian greens need rich, fertile, nonacidic soil. All do well in containers and full sun, but lettuces need shade in high summer.

**Sowing and planting out** Leafy salads germinate quickly in warm conditions, but avoid extremes of heat or cold. Sow salads in modules under cover from early spring; sow spinach, Swiss chard, and bok choy outdoors in light shade. Successional sowings of small numbers of seeds help to guarantee a continuous supply of leaves. Plant out module-grown seedlings when their roots have filled the container, and water well. Thin directly sown seedlings to the appropriate spacing.

Tender herbs, such as basil, are often grown from seed; hardy herbs are usually bought as young plants. Sow seeds under cover in early spring; plant out after the last frost.

**Care and potential problems** Keep rows of salads and leafy crops weed-free and don't let them dry out, to discourage bolting. Protect early or late crops from frost with cloches or floating row cover. Trim herbs regularly to keep them productive; water containers frequently.

Slugs and snails, as well as clubroot and caterpillars on brassicas, are the biggest problems. Lettuces are prone to fungal rots in wet weather; mildew can spoil spinach crops.

**Harvest and storage** Leafy salads are best eaten fresh. Cut hearting lettuces and bok choy at their base; pick leaves as needed from loose-leaf lettuces, cut-and-come-again crops, spinach, and chard. Use herbs fresh, or dry or freeze them.

### Sowing depths and spacing

| CROP | SOWING DEPTH | SPACING | |
|---|---|---|---|
| | | Plants | Rows |
| Lettuce | ½ in (1 cm) | 6–12 in (15–30 cm) | 6–12 in (15–30 cm) |
| Mizuna/mibuna | ½ in (1 cm) | 4–6 in (10–15 cm) | 6 in (15 cm) |
| Arugula | ½ in (1 cm) | 6 in (15 cm) | 6 in (15 cm) |
| Spinach | 1 in (2.5 cm) | 3–6 in (8–15 cm) | 12 in (30 cm) |
| Chard | 1 in (2.5 cm) | 8 in (20 cm) | 18 in (45 cm) |
| Basil | ¼ in (0.5 cm) | 8 in (20 cm) | 8 in (20 cm) |
| Parsley | ¼ in (0.5 cm) | 8 in (20 cm) | 12 in (30 cm) |
| Cilantro | ¼ in (0.5 cm) | 8 in (20 cm) | 12 in (30 cm) |

Colorful red-leaved lettuce 'Great Dixter'.

## Cultivation tips

**Preventing lettuce and spinach from bolting** In hot weather and when the soil is dry, lettuces, spinach, and many other leafy crops bolt, which is when plants go to seed and leaves become bitter (*see left*). Prevent or delay this by keeping the soil moist with regular watering and by planting summer crops in light shade rather than full sun.

**Halting the spread of mint** With its underground runners, mint can become an invasive nuisance in the garden, so it is best to grow it in a container or at least in a pot sunk into the soil. The latter will help to prevent it from taking over, but may not confine it forever.

**Propagating perennial herbs** Renew the vigor of old woody perennial herbs by digging them up in late summer and dividing them. Using pruners, cut the plants into small sections with plenty of healthy roots and leaves, which you can then replant. This works particularly well for thyme, chives, and oregano, but division is not suitable for shrubby herbs, such as sage and rosemary.

## Crops to choose

**Spinach** A very nutritious crop and easy to grow. Harvest baby leaves to use in salads, or mature leaves for steaming.

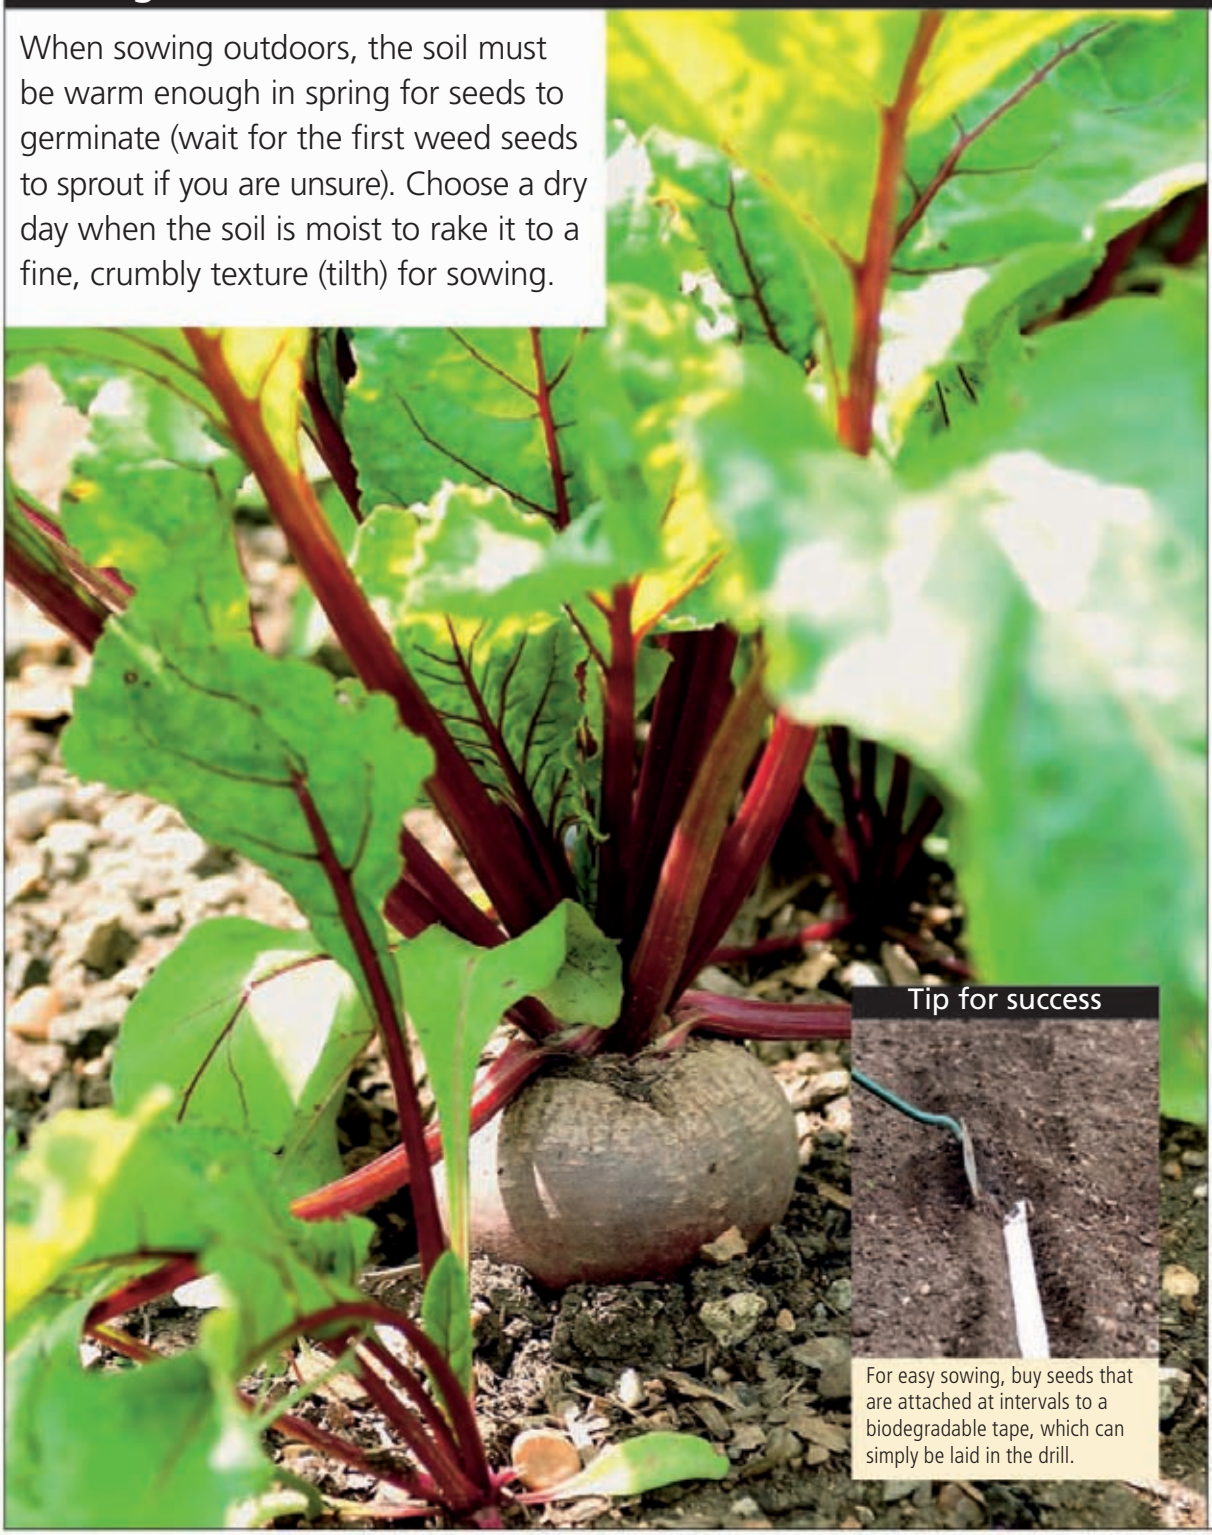
**Swiss chard** This striking crop is grown for its colored stems, which look good on the plate, and can be steamed or eaten fresh.

**Apple mint** Furry, with a mild, sweet flavor, this is the best mint for flavoring vegetables and to stroke as you walk past.

**Purple sage** This bushy, purple-tinged plant is so attractive that it is often planted in flowerbeds. It tastes good, too.

# Sowing beet seeds outside

When sowing outdoors, the soil must be warm enough in spring for seeds to germinate (wait for the first weed seeds to sprout if you are unsure). Choose a dry day when the soil is moist to rake it to a fine, crumbly texture (tilth) for sowing.



**Tip for success**

For easy sowing, buy seeds that are attached at intervals to a biodegradable tape, which can simply be laid in the drill.

1 For a straight row, pull a string line tight across the seed bed and make a V-shaped drill by dragging the corner of a hoe along the string. Make the drill about 1 in (2.5 cm) deep for beet seeds (the depth varies for different crops).

2 Pour seeds into the palm of your hand and sow them one at a time at 2-in (5-cm) intervals along the row. (Spacings vary for different seeds according to their size; tiny seeds should be sown as thinly and evenly as possible.)

3 As soon as sowing is complete, use the back of a rake to push the soil gently over the drill. Mark the row clearly with a plant label so you know what you have sown where, and don't disturb the germinating seeds.

4 Keep rows free of weeds. Remove excess seedlings by pulling them out with their roots, or pinching them off at soil level when they are large enough to handle. This ensures that the remaining plants have enough space.

# Growing zucchini from plug plants

1 Buy compact, green plants with a healthy root system. Water well and plant out or pot on immediately to avoid slowing their growth. Beware of buying zucchini and other half-hardy plants before the risk of frost has passed.

2 Carefully remove each seedling from its packaging and, holding the root ball rather than the delicate leaves, plant them into prepared soil so that the top of the root ball is just below soil level.

3 Gently firm the soil around each plant so that it is stable, and water well to help it get established. Add a mulch of organic material around each plant (but not touching the stem) to retain soil moisture and suppress weeds.

4 Label, and add supports for plants that need them as they grow. Cloches are often useful to protect young plants from cold and windy weather. Continue to water the plants regularly until they are established.

# Growing first early potatoes

1 In late winter, place your seed potatoes in egg cartons or trays with the maximum number of buds (eyes) pointing upward. Stand the boxes in a cool, light place indoors for about six weeks to produce sturdy, dark sprouts.

2 When shoots reach about 1 in (2.5 cm) long, in early spring, mark a row in prepared soil. At 12-in (30-cm) intervals, dig holes about 4 in (10 cm) deep and plant a single tuber in each, with its shoots pointing upward.

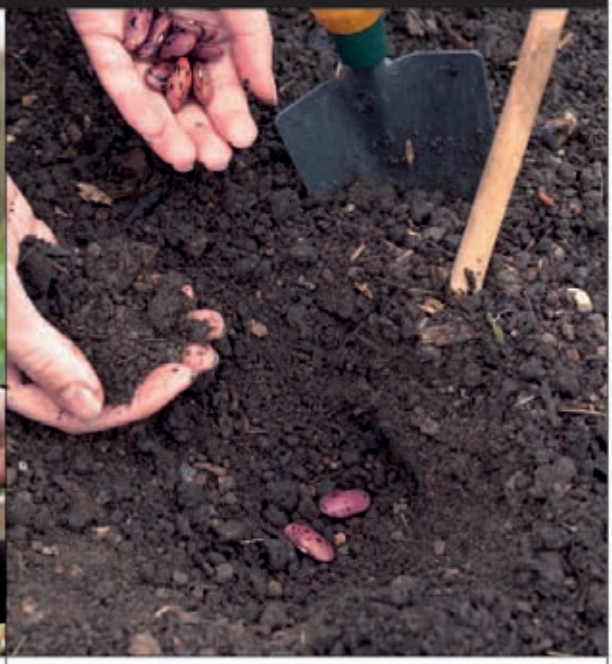
3 Fill each hole with soil, rake over the row, and mark its position. A general-purpose fertilizer can also be applied at the specified rate on either side of the row at this stage, or it may be worked into the soil before planting.

4 Tubers exposed to light will turn green, making them toxic and inedible. To avoid this, earth up the plants as they emerge by mounding soil around their stems to a height of around 6 in (15 cm).

## Growing runner beans

Runner beans grow best in rich, fertile soil, so prepare your site by digging in plenty of organic matter at least two weeks before planting. Plant scented flowers, such as sweet peas, nearby to attract pollinating insects to the garden.

1 Support is vital for these climbing plants. Build a teepee from eight canes, ideally at least 7 ft (2.2 m) long, pushed firmly into the soil about 12 in (30 cm) apart, in a circle. Tie the canes securely at the top and again halfway down.



2 From late spring, when the soil is at least 54°F (12°C), plant two seeds at a depth of 2 in (5 cm) by each cane and water thoroughly. In cold areas or where the soil is heavy, sow the seeds in deep pots indoors in mid-spring.

3 After germination, remove the weaker seedling. Twist the remaining plant around its cane and tie it in with twine. A companion sweet pea plant will attract insects to the runner bean flowers, promoting a good crop.

4 It is important to pick runner beans regularly (at least twice a week), when they are young and tender, because overly mature pods are less appetizing and suppress the formation of new flowers.

# Planting tomatoes in a growing bag

Growing bags dry out rapidly, but the volume of potting mix can be increased, and the need to water reduced, by planting into open-ended pots inserted into holes in the bag, as shown here.

## Tip for success

Other summer crops, such as lettuce, suit growing bags, taking only 8–12 weeks from seed to the cropping stage.

1 Using a knife, carefully cut three openings in the top of the growing bag and cut drainage holes in the base. If using bottomless pots (buy ready-made, or make your own), insert them into the openings and fill with soil.

2 When the plants are hardened off and the first flowers are about to open, plant into the bag or the pots so that the top of the root ball is just below the soil surface. Firm the soil around the roots and water well.

3 Add canes or strong wires for support. Take care to pinch out all fast-growing sideshoots between the leaves and stem—they divert valuable energy away from fruit production. Apply a liquid tomato fertilizer weekly.

4 Tie in the main stems with twine as they grow. Stop the plant from growing taller by removing the growing tip, two leaves beyond the fifth or sixth cluster (truss) of fruit. This diverts the plant's energy into the last fruits of the season.

# Growing chard in a container

A large pot filled with the glossy green leaves and neon-colored stems of chard 'Bright Lights' will add color to any patio. Harvest the baby leaves for salads when young, or allow them to mature for steaming and stir-frying.

## Tip for success

Test different layouts in your container while the plants are still in their own pots to help create the best color display.

1 Position the empty pot in a sunny, sheltered spot. Ensure that the container has drainage holes, cover the base with a layer of crocks, and add multipurpose potting mix to within about 1 in (2.5 cm) of the container's lip.

2 Water the young chard plants and carefully remove them from their pots, holding them by the roots rather than the leaves. Gently tease out the roots to help them establish quickly, and space them about 4 in (10 cm) apart.

3 Place the plants into holes made in the potting mix at the correct spacing, checking that the top of the root ball is just below soil level. Gently firm soil around each plant and water the container thoroughly.

4 Water the chard regularly to keep the large leaves firm and in good condition, especially during hot summer weather. You can also apply a nitrogen-rich fertilizer to help maintain vigorous healthy growth.

## Intercropping lettuce and corn

Planting a slow-growing and a fast-maturing crop together in a grid pattern is an efficient way to make the most of limited space. Lettuces can be grown among sweet corn plants and picked before the cobs mature.

1 Measure and mark out a grid of 18-in (45-cm) squares. Use bamboo canes to mark the lines in the soil. This block arrangement is also ideal for maximizing the wind pollination of sweet corn.

2 Transplant one young corn plant in the corner of each square. Firm the soil around the base of each plant. (Corn plants are tender, so they may have to be raised from seed under cover, *see p.217.*)

3 Mix the lettuce seed with fine sand and scatter thinly in between the corn plants. Rake over carefully. The lettuces will mature in 8–12 weeks and fill the gaps in between the corn plants.

4 Thin the lettuce seedlings to 3–4 plants per square. Sweet corn takes at least 16 weeks to produce mature cobs, but the lettuce can be harvested long before the corn casts too much shade on them.

## Planting an herb garden

This formal herb feature takes only a day to build and a season to mature. Here, bricks have been used to edge the beds and divide them into quarters. A potted bay tree forms the centerpiece.

1 Mark out a cross with pegs and string. Dig trenches following the string lines, just wider and not quite as deep as the bricks to allow space for the bricks to settle. Use a hammer handle to firm in the bricks.

2 Finish the last quarter and bed the bricks down securely, packing the soil firmly against them (no need to mortar them in). If you wish to have a plant in the center of the feature, make sure you leave space for it.

3 Arrange the plants in their pots before they go in the ground, so you can adjust the spacing if required. Water each plant thoroughly before removing it from its pot. Make planting holes and insert the plants. Water well.

4 Finish off the design with a central plant—a bay tree, which can be clipped into shape, has been used here. Water all the plants regularly until they are fully established, especially in hot, dry weather.

# Vertical vegetable garden

Vertical space is often underused, but it has great potential in small gardens, increasing the space for growing a range of crops. Attaching pots of herbs and bush varieties of vegetables to a sturdy wire mesh can turn a bare sunny wall into a riot of color, and they are simple to care for and convenient to harvest. Vigorous climbing beans, squashes, and nasturtiums can be planted in large containers at the base of the wall and are easy to train up the mesh for a fabulous, lush display.

## Garden basics

**Size** 6 x 7 ft (1.8 x 2.2 m)
**Suits** Any sunny location with a wall or fence as a backdrop
**Soil** Light, multipurpose potting mix
**Site** Wall in full sun

## Shopping list

- 2 x eggplant 'Mohican'
- 3 x basil 'Sweet Genovese'
- 3 x basil 'Red Rubin'
- 3 x tomato 'Tumbling Tom Red'
- 1 x cucumber 'Masterpiece'
- 1 x zucchini 'Tromboncino'
- 3 x runner bean 'Wisley Magic'

## Planting and aftercare

Attach wood battens to the wall and secure a sturdy wire mesh to them. Drill holes in the sides of plastic pots and window boxes and thread galvanized wire through them before planting. After the risk of frost has passed, fill the pots with a lightweight potting mix, plant with hardened-off plants, secure pots to the mesh, and arrange larger ones at the base of the wall. Leave space for plants to develop, and train climbing crops up the mesh. Water the plants frequently because they will dry out rapidly in their exposed position. Tie in climbing plants as they grow, and harvest frequently to encourage further crops.

Eggplant 'Mohican'

Basil 'Sweet Genovese', 'Red Rubin'

Tomato 'Tumbling Tom Red'

Cucumber 'Masterpiece'

Zucchini 'Tromboncino'

Runner bean 'Wisley Magic'

# Hanging herb and vegetable basket

Vegetable gardening does not get much more convenient than picking juicy cherry tomatoes and fragrant herbs from just outside your back door. Hanging baskets are often associated with bedding plants, but why not try planting a combination of cascading cherry tomatoes, vibrant nasturtiums, and delicious herbs instead? Kept fertilized and watered, they will look great over a long season and provide tasty fresh produce for the kitchen as well.

## Container basics

**Size** Basket at least 10 in (25 cm) in diameter
**Suits** Area close to the kitchen
**Soil** Multipurpose potting mix
**Site** Wall in full sun and sheltered from strong winds

## Shopping list

- 1 x chocolate peppermint 'Chocolate'
- 1 x parsley 'Forest Green'
- 1 x lemon thyme 'Golden Lemon'
- 1 x tomato 'Tumbler'
- 1 x chives
- 1 x nasturtium 'African Queen'

## Planting and aftercare

Ensure that drainage holes have been made in the base of the basket. Place a layer of lightweight potting mix in the bottom of the basket, then position the plants, still in their pots, to see where they will look best. Remember that trailing plants should be near the edge. Once you have settled on a design, water the plants well, remove them from their pots, and place in the basket. Fill the gaps with potting mix, firming around the plants, and water the basket thoroughly. Hang it on a sturdy hook and water regularly. Once tomatoes begin to set, apply a liquid tomato fertilizer weekly.

Peppermint 'Chocolate'

Parsley 'Forest Green'

Lemon thyme 'Golden Lemon'

Tomato 'Tumbler'

Chives

Nasturtium 'African Queen'

# Cut-and-come-again window box

Even without a garden, it is possible to grow a good supply of tasty baby salad leaves. Cut-and-come-again salads are one of the quickest and easiest crops to grow from seed and, when grown in a window box, could not be more convenient to care for and harvest. Try growing your own mix of lettuce, Asian greens, and arugula to create a peppery salad, which tastes wonderfully fresh when it has gone from plant to plate in a matter of seconds.

## Window box basics

**Size** 20 x 6 in (50 x 15 cm)
**Suits** Window sill where a window box can be secured
**Soil** Good multipurpose potting mix
**Site** Window sill with access for watering, in full sun or partial shade

## Shopping list

- 1 x packet mibuna seeds
- 1 x packet mizuna seeds
- 1 x packet lettuce 'Oakleaf' or 'Salad Bowl Mixed' seeds
- 1 x packet arugula seeds

## Planting and aftercare

Choose a window sill in sun or partial shade, which can be reached easily for watering and harvesting. Make sure the window box is secured and has drainage holes in the base. Add a layer of crocks to the box and fill it to within ¾ in (2 cm) of the top with multipurpose potting mix. Blend the different seeds together in a bowl and sow thinly from the palm of your hand from mid-spring until late summer. Cover with a thin layer of potting mix and water well. Germination is rapid and the first leaves can be cut with scissors after 3–5 weeks, leaving a 2-in (5-cm) stump to regrow. Two or three further harvests can be cut at 3–5-week intervals. Water the window box regularly for a healthy crop.

Mibuna

Mizuna

Lettuce 'Oakleaf'

Additional plant idea

Arugula 'Rocket Wild'

# Decorative climbing display

Few flower and vegetable combinations could be more eye-catching than this mix of exotic purple blooms and bulging orange squashes. The vigorous growth of squash is perfect for training up a fence and provides an interesting contrast to the delicate foliage of the climbing passion flower and cup-and-saucer plants. All of these plants flourish in summer heat, and will perform best in warmer areas with a long growing season.

## Border basics

**Size** 6 x 6 ft (2 x 2 m)
**Suits** Vegetable or ornamental garden with a fence or trellis as a backdrop
**Soil** Fertile, moist, but well-drained
**Site** Border in front of fence or trellis in full sun

## Shopping list

- 1 x squash 'Uchiki Kuri' or 'Jack Be Little'
- 1 x passion flower (*Passiflora caerulea*)
- 1 x cup-and-saucer plant (*Cobaea scandens*)

## Planting and aftercare

Sow squash and cup-and-saucer plant seeds under cover in mid-spring, in either a warm room or a heated propagator. Passion flowers are readily available as plants and will persist as perennial climbers in warm regions. Attach wires or trellis to a bare fence, so the climbing plants can be tied in or use their own tendrils for support.

After the last frost date, plant the young plants about 12 in (30 cm) away from the base of the fence, about 18 in (45 cm) apart, and water them well. Tie the stems to the supports when they are long enough, after which the passion flower and cup-and-saucer plant should find their own way, while the squash may need further tying in. Water the squash regularly once fruits have formed.

Squash 'Uchiki Kuri'

Passion flower (*Passiflora*)

Cup-and-saucer plant (*Cobaea*)

Alternative squash

Squash 'Jack Be Little'

# Exotic vegetable raised bed

If you have a sheltered, sunny wall that absorbs the sun's heat during the day and warms the surrounding air at night, take advantage of this microclimate to grow exotic crops. This raised bed has been filled with heat-loving tomatoes, peppers, eggplants, and feathery-leaved garbanzo (chickpea) plants, as well as cucumbers and sweet potatoes that scramble up the wall. Some of these vegetables only crop well in hot summers, but they make attractive curiosities that are fun to try.

## Border basics

**Size** 6 x 3 ft (2 x 1 m)
**Suits** Any style of garden
**Soil** Fertile, moist, but free-draining
**Site** Border in front of a wall in full sun, in warm regions

## Shopping list

- 1 x eggplant 'Moneymaker'
- 1 x cucumber 'Carmen'
- 1 x sweet pepper 'Gypsy'
- 1 x tomato 'Summer Sweet'
- 1 x garbanzo 'Principe'
- 1 x sweet potato 'Beauregard'

## Planting and aftercare

Sow seeds of tomatoes, cucumbers, sweet peppers, and eggplants under cover in spring. Once the risk of frost has passed, harden the young plants off and plant them out in the raised bed. It is a good idea to soak the garbanzos in regularly changed water for a few days until they sprout before planting them in their final positions. Plant the sweet potato "slips" with about 2 in (5 cm) of stem above the soil and, as with the other young plants, water well. Attach wire mesh to the wall and train the cucumber and sweet potato stems through it. Once the first fruits have set, fertilize weekly with a tomato fertilizer that is high in potash. Crops should be ready to harvest in late summer.

Eggplant 'Moneymaker'

Cucumber 'Carmen'

Sweet pepper 'Gypsy'

Tomato 'Summer Sweet'

Garbanzo 'Principe'

Sweet potato 'Beauregard'

# Courtyard vegetable garden

Even a modest corner of the garden can be enough to grow an interesting range of vegetables that will crop well over a long season. Here, cordon tomatoes and runner beans have been trained up the wall and fence to make the best use of the vertical space. Edging the path is a densely sown crop of cut-and-come-again lettuce. Red cabbage and sweet corn will extend the harvest into late summer and early fall, the zucchini in the pot until mid-fall.

## Border basics

**Size** 12 x 6 ft (4 x 2 m)
**Suits** Courtyard garden
**Soil** Fertile, moist, but free-draining
**Site** Corner of garden, sheltered by a wall or fence, in full sun

## Shopping list

- 3 x tomato 'Gardener's Delight'
- 3 x runner bean 'Liberty'
- 1 x zucchini 'Burpee's Golden'
- 9 x sweet corn 'Swift'
- 1 x packet lettuce seed 'Salad Bowl Mixed'
- 3 x cabbage 'Marner Early Red'

## Planting and aftercare

Prepare the area by digging in plenty of organic matter, ideally in fall. Buy plug plants or, where there is space under cover, sow tomato, runner bean, red cabbage, and sweet corn seeds in pots, harden them off, and plant out after the risk of frost has passed. Plant tomatoes in a growing bag because they thrive on the rich soil, adding canes for support and pinching out sideshoots as they grow. Give the runner beans wires to climb up. Plant sweet corn in a block to aid pollination, and direct-sow a few lettuce seeds regularly to ensure a continuous crop. Water young plants in, and continue watering and fertilizing regularly those in growing bags.

Tomato 'Gardener's Delight'

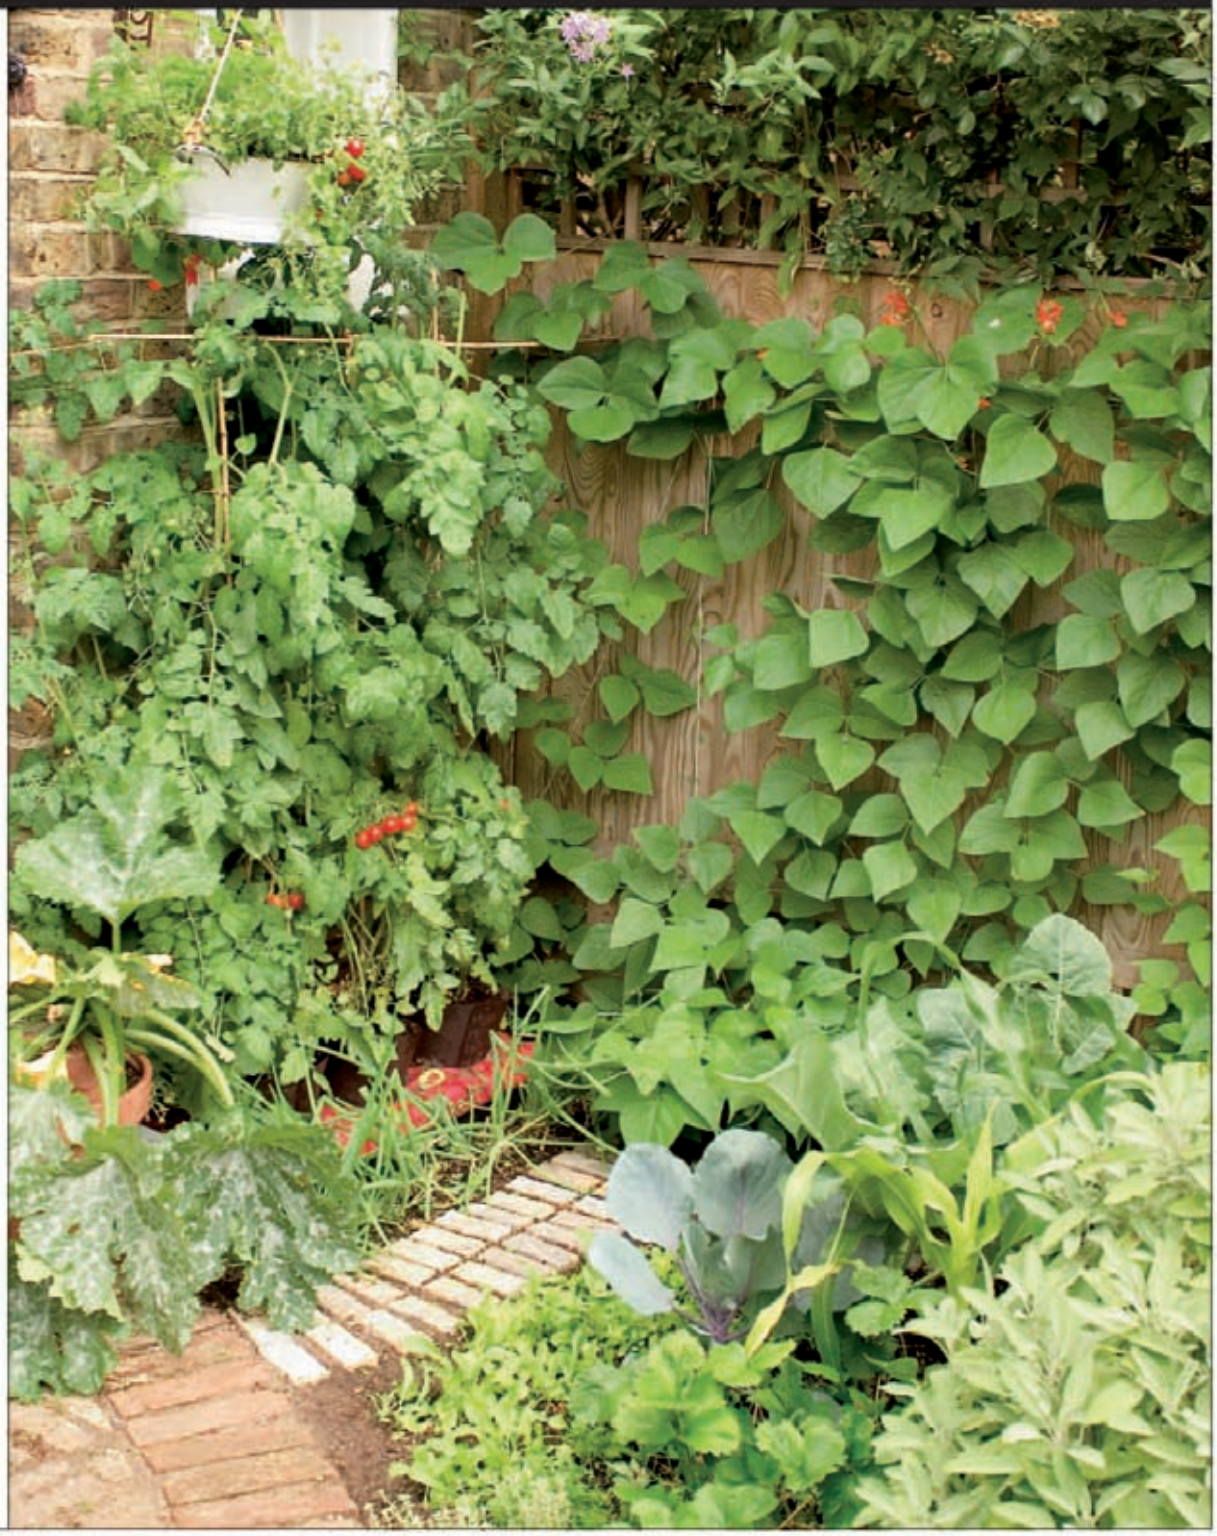
Runner bean 'Liberty'

Zucchini 'Burpee's Golden'

Sweet corn 'Swift'

Lettuce 'Salad Bowl Mixed'

Cabbage 'Marner Early Red'



# Pretty potager

Formal patterns and exquisite color combinations characterize the French-style potager, where vegetables look as attractive as ornamental plants.

Planting a potager is not difficult, but it does require careful planning to select and arrange colored varieties that mature to provide interest throughout the year. Here, sweet corn and runner beans add valuable height to a scheme dominated by gray and purple foliage.

## Border basics

**Size** 20 x 25 ft (6 x 8 m)
**Suits** An area with easy wheelbarrow access and a water supply
**Soil** Fertile, moist, and free-draining
**Site** Large open plot in full sun, with shelter from strong winds

## Shopping list

- 1 x packet runner bean 'Liberty' seed
- 1 x packet sweet corn 'Lark' seed
- 1 x packet cabbage 'Red Jewel' seed
- 1 x packet fava bean 'The Sutton' seed
- 1 x packet kale 'Red Russian' seed
- 1 x pack shallot 'Golden Gourmet' sets

## Planting and aftercare

Prepare the soil by adding plenty of well-rotted manure the fall before planting. Draw out your design on paper, calculating the number of plants required to fill each row and what they can be replaced with once harvested. Plant the seeds in spring, harden off where required, and transplant into neat rows in early summer, adding supports for the runner beans. Water the young plants well, tie climbers to supports, and protect from pests as necessary. Harvest crops as they mature and plan to have replacement plants ready to fill the empty ground as soon as possible to maintain the garden's appearance.

Runner bean 'Liberty'

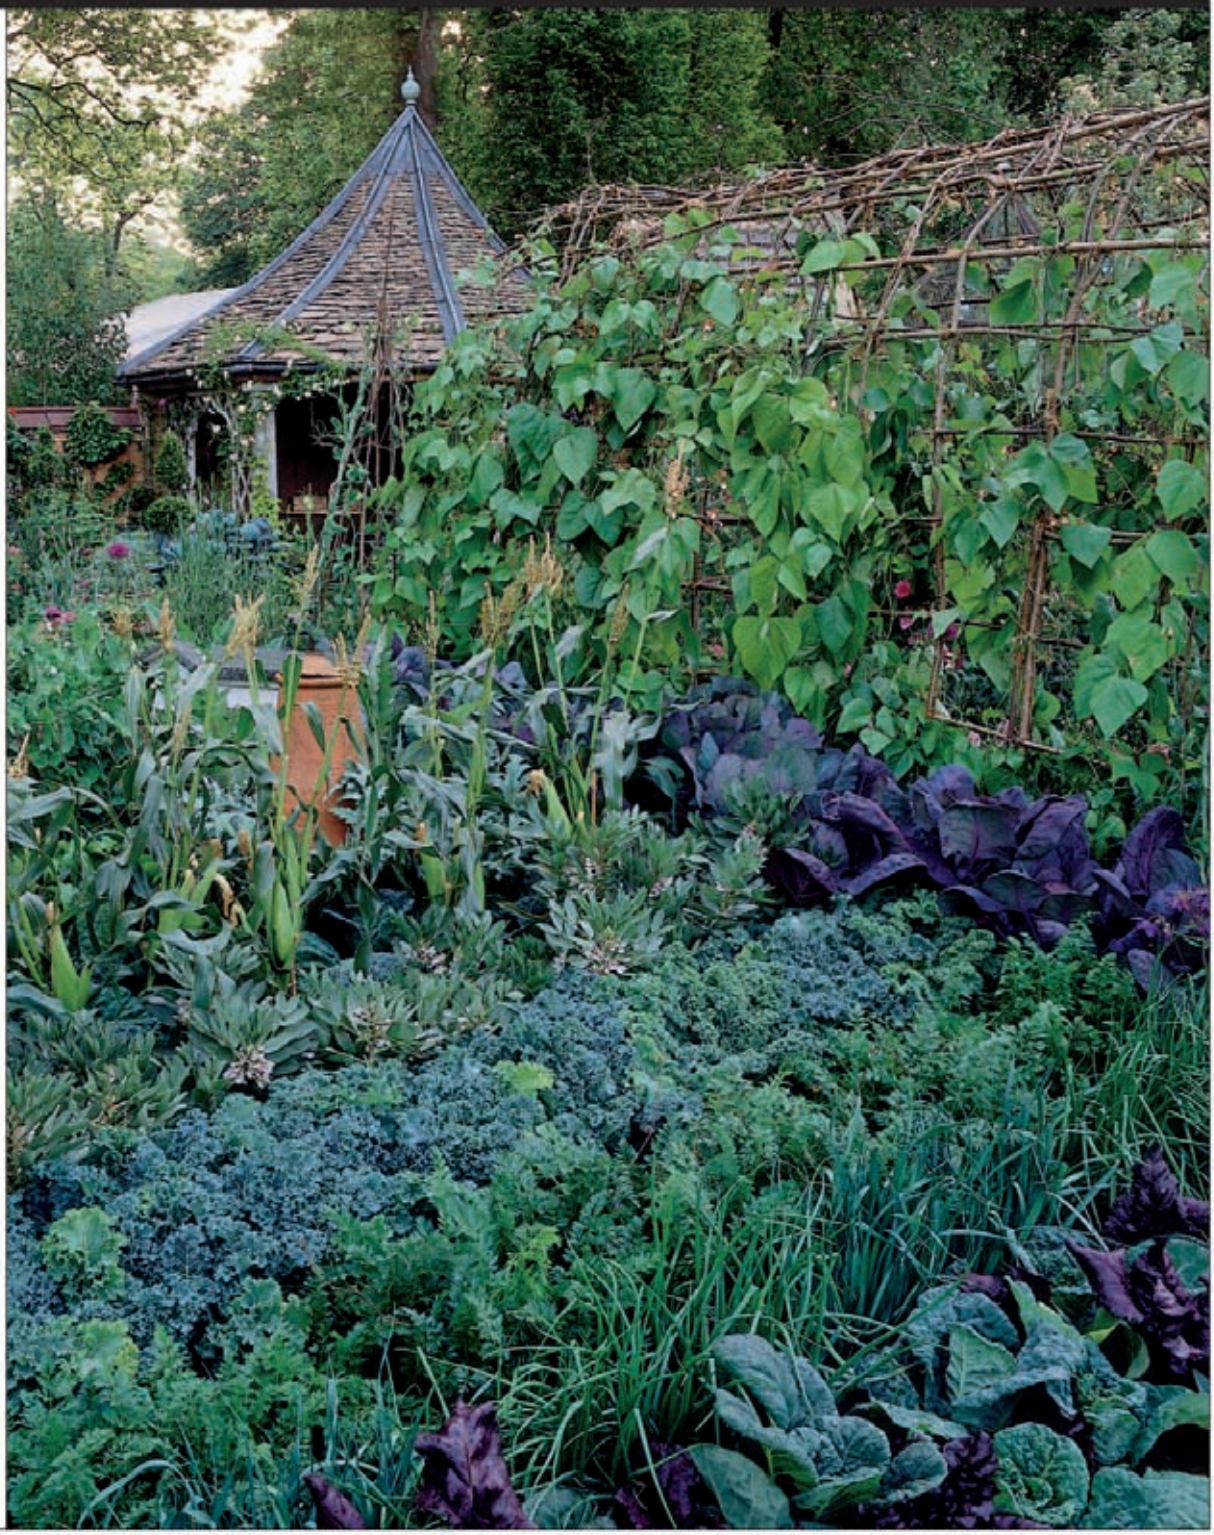
Sweet corn 'Lark'

Cabbage 'Red Jewel'

Fava bean 'The Sutton'

Kale 'Red Russian'

Shallot 'Golden Gourmet'



# Garden allies

Some wild creatures help to pollinate plants, break down compost, and prey on pests, so make these friendly visitors welcome in your garden.

**Busy bees** The flowers of many vegetables, such as runner beans, need to be pollinated by insects in order to set their crop. Bees are excellent pollinators, so include ornamental flowers in your vegetable garden to entice them in.

## Friendly pest predators

Not all insects found in the vegetable garden are pests, and many of them prey on harmful insects that can destroy entire crops if left unchecked. It is, therefore, well worth encouraging the good guys into your vegetable garden to try to achieve a natural balance and keep pest numbers low. Remember, too, that many pesticide sprays, even organic ones, kill beneficial insects as well as pests, and are best used only as a last resort.

**Hoverflies** Sometimes mistaken for bees, adult hoverflies are great pollinators, while the larvae feed voraciously on insect pests.

**Ladybugs** The adults are familiar friends, but the less appealing larvae enjoy nothing better than feasting on juicy aphids.

**Lacewings** The delicate appearance of the adult lacewing belies the enormous appetites of its larvae for common garden pests.

## Helpful animals and birds

Although they may be elusive, many larger garden residents, such as birds and toads, can be a gardener's best friend, feeding on slugs and all kinds of other unwelcome visitors. Birds soon flock to gardens where food is provided, and different species will pick off insects and even feed on snails during a visit. Create suitable habitats for all kinds of creatures and they will repay you with a healthier and more productive garden.

**Song thrushes** These birds break snails from their shells, so plant a berry-bearing shrub or tree on your patch to give them winter food, too.

**Brandling worms** Smaller and redder than the usual earthworm, these creatures rapidly reduce vegetable matter to compost.

**Frogs and toads** Even a small pond can become home to a number of frogs and toads, which will help to keep the slug population in check.

# Gallery of weeds

## Perennial weeds

**Field bindweed** (*Convolvulus arvensis*) This climber, with its pretty white flowers and heart-shaped leaves, will regrow from the tiniest fragment of root and quickly spread.

**Bramble** (*Rubus*) A scrambling shrub, with long, arching, prickly stems, that can rapidly become invasive and hard to remove. The stems also re-root at the tips.

**Creeping buttercup** (*Ranunculus repens*) This low-growing plant with yellow flowers spreads by runners that form a dense mat of shallow roots, which are relatively easy to remove.

**Couch grass** (*Agropyron repens*) This leafy grass spreads incredibly fast by tough, underground roots that can be hard to dig up intact. It will regrow from any pieces left in the soil.

**Dandelion** (*Taraxacum officinale*) Catch the rosettes of toothed leaves while small and easy to remove—once the taproot grows and the seeds disperse, the job is much harder.

**Dock** (*Rumex*) Large pointed leaves and tall flower spikes grow above a fleshy taproot that extends deep into the soil and takes considerable effort to remove once established.

**Ground elder** (*Aegopodium podagraria*) The creeping roots make this a pernicious garden weed, easily recognized by its elderlike leaves and clouds of white flowers.

**Stinging nettle** (*Urtica dioica*) The coarse, jagged leaves are covered with stinging hairs. The bright yellow, creeping roots are easy to see, but a challenge to remove.

**Horsetail** (*Equisetum*) Almost impossible to eradicate, the dark brown, bootlace-like roots of these feathery plants can extend several yards (meters) underground.

## Annual and biennial weeds

**Annual meadowgrass** (*Poa annua*) This insignificant-looking, low-growing grass colonizes any available space, including cracks in paving, so remove it before it sets seed.

**Ragwort** (*Senecio jacobaea*) The yellow daisy flowers of this tall plant are produced in its second year, followed by fluffy white seeds that colonize open ground.

**Common chickweed** (*Stellaria media*) Rather delicate, with charming little white, starlike flowers, this weed establishes and sets seed rapidly, and its sprawling habit smothers seedlings.

**Groundsel** (*Senecio vulgaris*) The white fluffy seeds of this weed float on the breeze, so it can spread far and wide. Remove plants before the tiny yellow flowers mature.

**Shepherd's purse** (*Capsella-bursa pastoris*) A rosette of cut-edged leaves gives rise to a spike of small white flowers, which quickly form heart-shaped seed capsules.

**Hairy bittercress** (*Cardamine hirsuta*) Best pulled up as a seedling, when it has small, watercress-like leaves, because the flower stem rapidly forms long seed pods.

**Cleavers** (*Galium aparine*) This scrambling weed is covered with little hooked bristles that enable it to climb through plants. Uproot it rather than pulling the stems.

**Fat hen** (*Chenopodium album*) The gray-green, diamond-shaped leaves of this common weed are easily recognized. It quickly grows tall, with a loose flower spike at its tip.

**Plantain** (*Plantago*) Low-growing rosettes of almost leathery leaves turn up in beds, paving, and lawns. Remove them before the little bottlebrush flowers are produced.

# Dealing with pests

Every garden has its share of pests, so don't panic and reach for the insecticide spray at every sighting. Healthy plants can usually tolerate them, and some are also food for beneficial insects, which you can encourage into your garden.

**A healthy balance** Help plants stay healthy by providing plenty of water and rich, well-drained soil, and prevent a buildup of pests by planting each crop in a different part of the garden every year. Encourage beneficial creatures, such as birds, hoverflies, and frogs, with suitable food and habitats. This helps achieve a natural balance, where predators keep pest numbers at an acceptable level, and there is less need for chemical intervention.

**Control strategies** Check plants regularly and pick off any unwelcome arrivals immediately. If you anticipate a problem, put a barrier, such as floating row cover for carrot flies, in place, or grow companion plants alongside the crop to entice beneficial insects or confuse pests. If necessary, use chemical sprays in the evening when bees and other beneficial insects are not flying. Sticky sheets are useful in the greenhouse, as are biological controls, which introduce a predatory organism to kill the pests.

Sticky sheets in the greenhouse help to control airborne pests.

## Keeping out animal pests

Large animal pests can devastate a vegetable patch overnight, so where you anticipate a problem, the best way to stop them from reaching your plants is to create a physical barrier. Deer and rabbits need fences to keep them at bay, but there are a number of cheap and easy ways of outwitting slugs, snails, mice, and birds.

- Halved plastic bottles with copper tape around the base protect young plants from slugs, snails, and birds.
- Netting supported with canes or wire keeps out birds; a fine net separates egg-laying butterflies from brassicas.
- Tightly secured netting deters burrowers like rabbits (*see opposite*), which eat roots, brassicas, and peas.

Plastic bottles and copper tape deter slugs.

Prevent bird damage with netting.

Floating row cover keeps out carrot flies.

## Gallery of pests

**Aphids** Sap-sucking insects (greenflies, blackflies) weaken growth and carry diseases. Encourage birds and insect predators, pick off small groups, or use a suitable insecticide.

**Rabbits** Keep these voracious vegetable eaters out of the garden with a small-meshed fence that extends 1 ft (30 cm) underground to prevent them from burrowing in.

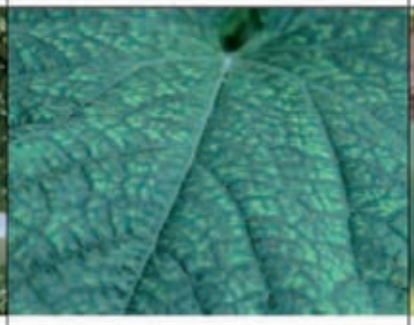
**Carrot flies** Cover crops with floating row cover, sow carefully to reduce the need for thinning, or grow resistant varieties to prevent carrot fly larvae from tunneling into roots.

**Potato cyst eelworm** These microscopic, sap-sucking nematodes cause potato leaves to discolor and die. Avoid replanting the same crop where an infestation has occurred.

**Caterpillars** Different parts of various plants may be damaged by caterpillars. Pea moth caterpillars (*above*) live inside the pods. Net crops to exclude egg-laying adults.

**Flea beetles** These tiny black beetles eat holes in the leaves of brassicas, turnips, radishes, and arugula. Keep them at bay by covering seedlings with floating row cover.

**Whiteflies** Treat greenhouse whitefly with the biological control *Encarsia formosa* (parasitic wasp), and the brassica whitefly with a suitable insecticide.



**Red spider mites** Small mites cause mottling on leaves, particularly in the greenhouse. Mist plants to increase humidity, and use the predatory mite *Phytoseiulus persimilis*.

**Slugs and snails** Protect vulnerable plants, and try beer traps and flashlight hunts. Nematode biological controls are less harmful to other animals than slug pellets.

# Dealing with diseases

Just like people, strong, healthy plants are more able to fight off infection than weak, malnourished ones. Here's how to keep yours in shape.

**Prevention is better than cure** Good cultivation is as much a part of fighting diseases as recognizing and treating them, and with few fungicides available to the amateur, preventative measures are essential.

Plants require a ready supply of nutrients and water to sustain healthy growth, so add plenty of organic matter to the soil to release nutrients and help retain moisture. Additional watering may also be needed, particularly in hot weather. It is important not to forget plants under cover and in containers, which rely on regular watering and feeding to sustain them. Damp conditions and poor air circulation can encourage fungal problems, such as damping-off of seedlings, so use free-draining potting mix and provide good ventilation when sowing indoors.

A neat garden also helps to keep diseases at bay. Ensure that sources of infection, such as dead leaves, harvested plants, and nearby weeds, are removed at the first opportunity. Burn or discard any diseased material; don't compost it because infection could spread.

Although not easy in a small garden, it is advisable to practice crop rotation, where related groups of crops are grown together and moved to a new bed each year, helping to prevent the buildup of diseases in the soil. Where diseases are known to be a problem, try growing resistant varieties. Be aware that plants brought into your garden can introduce disease, so check any purchases or gifts carefully before planting.

**Deficiency, not disease** Signs of nutrient deficiency, such as yellowing leaves and blossom end rot on tomatoes and peppers, are often mistaken for diseases. Learn to recognize these disorders, so that you can act quickly and minimize their effects. Sometimes the remedy is as simple as improving the water supply; other problems may need fertilizer added to the soil.

Use fresh seed starting mix and new or sterilized pots and trays to prevent damping-off disease.

Keep the garden well watered to encourage vigorous, healthy growth that is less susceptible to all kinds of infection.

Add lime to acidic soil before planting brassicas to increase the pH level and reduce the incidence of clubroot.

## Gallery of diseases and disorders

**Potato/tomato blight** Brown patches on leaves, fruits, and tubers, caused by a fungus that thrives in warm, wet weather. Grow resistant varieties or spray with copper-based fungicide.

**Sclerotinia** Fungus that causes brown, slimy rot with fluffy, white growth, predominantly on stems and fruits of various vegetables. Remove and burn or discard affected plants.

**Magnesium deficiency** Older leaves of various vegetables show yellowing between veins, especially in acidic soil or after heavy rains. Apply Epsom salts to the soil or as a foliar spray.

**Clubroot** This soil-borne slime mold infects brassicas, causing swollen roots, wilting foliage, and even death. Ensure good drainage, add lime to acidic soil, and choose resistant varieties.

**Blossom end rot** Dry conditions affect calcium uptake, which causes sunken, black patches at the tips of tomatoes and sweet peppers. Correct with adequate, regular watering.

**Powdery mildew** A wide range of crops are affected by these fungi, causing powdery white growth on leaves in dry soil conditions. Water the soil well, but not over the leaves.

**Onion white rot** This fungus persists in the soil for up to seven years and causes fluffy white growth on bulbs and roots and yellowing of leaves. Remove and burn infected plants.

**Rust** Orange or brown spots appear on the leaves and stems of various vegetable crops, particularly in damp weather. Remove infected leaves and grow resistant varieties.

**Botrytis** A fluffy, gray mold (or whitish spots on tomatoes) that enters plants through wounds or flowers. Remove dead and infected plant material to reduce risk of infection.

# Tall plants for sun (Ab–Cy)

**Abutilon *x* suntense**
This spectacular evergreen shrub is a fine choice for a sunny, sheltered site by a wall or fence. The hairy, gray-green leaves are shaped like those of a grapevine. In late spring, clusters of large, open, purple or white flowers cover the plant for many weeks.

**H**: 12 ft (4 m), **S**: 6 ft (2 m)
❄❄ ◊ ☼

**Acacia dealbata**
Reaching tree-sized proportions, this quick-growing evergreen has fernlike, sea green foliage. In sheltered spots, it produces scented, puffball-shaped, yellow flowers in late winter. If it grows too large, it can be pruned to size in spring.

**H**: 50 ft (15 m), **S**: 20 ft (6 m)
❄❄ ◊ ☼

**Arbutus unedo**
The strawberry tree is one of the best evergreen trees for a small garden. Shrubby when young, it has glossy, dark green leaves and bell-shaped, white or pink flowers in late fall, followed by strawberry-like fruits. The bark is reddish brown.

**H**: 30 ft (10 m), **S**: 20 ft (6 m)
❄❄❄ ◊ ☼

**Betula utilis *var.* jacquemontii**
With its light canopy and slender form, this silver birch suits small sites well. In winter, the dazzling white trunk with its peeling bark provides interest; catkins and young leaves are an attraction in spring. The leaves turn butter yellow before falling.

**H**: 50 ft (15 m), **S**: 23 ft (7.5 m)
❄❄❄ ◑ ◊ ☼ ☼

**Buddleja davidii '*Dartmoor*'**
Buddlejas are easy to grow and attractive to butterflies. In mid- to late summer, this graceful selection has reddish purple, cone-shaped flowerheads on long, arching stems, giving a weeping appearance. Prune in spring to keep under control.

**H**: 10 ft (3 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ☼

**Cestrum parqui**
An unusual shrub that is ideal for a warm, sunny wall. Its greenish yellow flowerheads, which are scented at night, appear from spring until frost. In cold areas, the plant may die to the ground, but will usually grow again from the root.

**H**: 10 ft (3 m), **S**: 6 ft (2 m)
❄❄ ◊ ☼

**Clematis '*Alba Luxurians*'**
One of the most rewarding clematis, this plant bears masses of small green-tipped white flowers with black anthers. Mature plants scramble up trellis to cover a wall or fence, but may overwhelm shrubs or small trees. In late winter, cut back to 8 in (20 cm).

**H**: 15 ft (5 m), **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

**Clematis cirrhosa**
Both evergreen and winter-flowering, this scrambling climber needs a sunny position, but is a quick-growing, easy plant. The shiny leaves make a good foil to the creamy, bell-shaped flowers, which can be speckled with red inside; fluffy seedheads follow.

**H**: 20 ft (6 m), **S**: 10 ft (3 m)
❄❄ ◑ ◊ ☼

**Clematis '*Perle d'Azur*'**
This plant makes an excellent addition to a small garden. It produces blue blooms in succession from midsummer to fall. The flowers are tinged violet as they open, but fade to blue as they age. Prune stems to 8 in (20 cm) in late winter.

**H**: 10 ft (3 m), **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

**Cornus kousa *var.* chinensis**
This must rank as one of the best garden plants. White or pink spring flowers with showy bracts are followed by red, strawberry-like fruits. Mature plants become more treelike and the flower displays ever more spectacular.

**H**: 22 ft (7 m), **S**: 15 ft (5 m)
❄❄❄ ◑ ☼

**Cotinus coggygria '*Royal Purple*'**
For lovers of colored foliage, this large shrub is a good choice. The rich red-purple leaves offset pale-colored flowers at the back of a border. In summer, wispy flowerheads may be produced; in fall, leaves gradually turn scarlet before falling.

**H**: 15 ft (5 m), **S**: 12 ft (4 m)
❄❄❄ ◑ ◊ ☼ ◑

**Cynara cardunculus**
The cardoon makes a fine plant even in small gardens, with its architectural form, silver-green foliage, and purple, thistlelike flowers, which attract bees. Place at the back of a border or use as a feature plant for a sunny corner. It dies to the ground in winter.

**H**: 6 ft (2 m), **S**: 4 ft (1.2 m)
❄❄ ◊ ☼

# Tall plants for sun (Ja–Tr)

**Jasminum nudiflorum**
Of all winter-flowering plants, this jasmine, usually grown as a climber, is perhaps the most reliable. Small, bright yellow flowers appear all winter on leafless, dark green stems. Hard frost will claim some blooms, but more are produced in mild spells.

**H**: 12 ft (4 m), **S**: 12 ft (4 m)
❄❄❄ 💧 ◑ ☼ ☼

**Juniperus communis '*Hibernica*'**
This conifer brings contrast, structure, and backbone to the small garden. With blue-green, prickly needles and a dense-growing, compact habit, it eventually forms a column several yards high, standing out from rounded and horizontal growth.

**H**: 15 ft (5 m), **S**: 24 in (60 cm)
❄❄❄ 💧 ◑ ☼ ☼

**Mahonia *x* media '*Buckland*'**
A useful shrub with glossy evergreen foliage, architectural form, and sweetly scented, bright yellow flowers held in spikes during the darkest winter months. The leaves are spiny; weeding beneath these plants is best done wearing gloves.

**H**: 12 ft (4 m), **S**: 10 ft (3 m)
❄❄❄ 💧 ◑ ☼ ☼

**Malus '*John Downie*'**
This compact crabapple is perhaps the best of its kind for a profusion of ornamental fruit in late summer. Yellow and orange in color, and large, the apples stand out from the deciduous foliage. In spring, pure white blossoms open from pink buds.

**H**: 30 ft (10 m), **S**: 20 ft (6 m)
❄❄❄ ◑ ☼ ☼

**Olea europaea**
The olive has become viable for temperate gardens, thanks to milder winters. It needs a sheltered site and as much sun as possible. It then makes a noble specimen with evergreen, silver-green foliage and a gray trunk. Small white flowers appear in summer.

**H**: 20 ft (6 m), **S**: 15 ft (5 m)
❄❄ 💧 ☼

**Photinia *x* fraseri '*Red Robin*'**
Evergreen photinia is at its glorious best in spring when the new bright copper-red growth appears; the large, smooth leaves retain a reddish tinge as they mature. It can be used as a hedge, since it responds well to pruning, and is quite compact.

**H**: 10 ft (3 m), **S**: 10 ft (3 m)
❄❄ ◑ ☼ ☼

**Prunus *x* subhirtella '*Autumnalis Rosea*'**
This tree suits those who like to enjoy the garden all year. Delicate, starry, pale pink flowers are produced between fall and spring. New spring growth is bronze-green, turning dark green as the leaves expand.

**H**: 25 ft (8 m), **S**: 20 ft (6 m)
❄❄❄ ◊ ◑ ☼

**Robinia pseudoacacia '*Frisia*'**
This deciduous tree's golden foliage provides dramatic contrast to other plants and illuminates dark urban gardens. Plants are usually grafted and have thorny, brittle stems; remove any suckers with green leaves that appear from the base.

**H**: 50 ft (15 m), **S**: 25 ft (8 m)
❄❄❄ ◑ ☼

**Romneya coulteri**
The tree poppy is a distinguished perennial that sends up tall yet slender, unbranched stems with silvery leaves that in mid- to late summer are topped by huge, scented, gold-centered flowers with delicate white petals.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ☼

**Solanum crispum '*Glasnevin*'**
This glamorous relative of the potato has scrambling stems, and makes a beautiful wall shrub. Small purple flowers with yellow centers appear in bunches all summer and associate well with clematis and roses. Plants respond well to light trimming in spring.

**H**: 12 ft (4 m), **S**: 6 ft (2 m)
❄❄ ◊ ☼

**Sorbus cashmiriana**
With its open growth habit, delicate foliage, and pink flowerheads in early summer, this tree is a good choice. In fall and early winter, the canopy is resplendent with clusters of shiny white fruits the size of small marbles that linger after the leaves have fallen.

**H**: 25 ft (8 m), **S**: 20 ft (6 m)
❄❄❄ ◊ ◑ ☼ ◑

**Trachelospermum asiaticum**
This evergreen climber is an excellent plant for the smaller garden; it does best in a sheltered spot. Small glossy leaves form dense cover up walls or over fences, and from early summer, clusters of starry, strongly scented cream flowers appear.

**H**: 12 ft (4 m), **S**: 10 ft (3 m)
❄❄ ◊ ◑ ☼ ◑

# Tall plants for shade (Ac–St)

**Acer palmatum *var.* dissectum *Dissectum Atropurpureum Group***
This is one of the most popular of small Japanese acers, with rich purple foliage. Slow-growing, it eventually forms a low, mounded shrub. The delicate leaves may be damaged by drying winds, so give it some shelter.

**H**: 6 ft (2 m), **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼

**Camellia sasanqua**
Most camellias bloom in spring, but those of *C. sasanqua* open in late fall. There are many cultivars, with scented single or semidouble flowers in white or pink. Train stems against a sheltered wall to protect the flowers from frost. Needs acidic soil.

**H**: 12 ft (4 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ☼

**Cercis canadensis '*Forest Pansy*'**
One of the most desirable of all deciduous shrubs, this is grown for its heart-shaped, rich purple foliage and clusters of purple, pealike flowers in spring. In fall, the leaves develop orange tints before falling. Grow it in a sheltered position.

**H**: 10 ft (3 m), **S**: 10 ft (3 m)
❄❄❄ ◑ ☼ ☼

**Daphne bholua '*Jacqueline Postill*'**
It is worth spending time finding a good spot for this evergreen daphne. In winter, it bears a profusion of waxy pink flowers with an intoxicating perfume that carries on the wind. It is best planted in a sheltered spot.

**H**: 10 ft (3 m), **S**: 5 ft (1.5 m)
❄❄ ◊ ◑ ☼

**Dicksonia antarctica**
This tree fern is one of the most recognizable of exotic plants. Its bright green fronds unfurl from tight croziers that appear from the tip of the slow-growing trunk. These plants need shelter, moisture, and protection in cold winters.

**H**: 20 ft (6 m), **S**: 13 ft (4 m)
❄❄ ◑ ☼

**Fatsia japonica**
Few hardy plants provide more impact than fatsia, with its large, leathery, hand-shaped leaves. In fall, heads of white flowers are followed by drooping bunches of shiny, black berries. It develops an elegant, upright habit with age.

**H**: 10 ft (3 m), **S**: 6 ft (2 m)
❄❄ ◊ ◑ ☼ ☼

**Hydrangea quercifolia**
Most hydrangeas are grown for their showy flowerheads, but this species is better known for its oaklike foliage, which develops dramatic autumnal colors before falling. Creamy white, conical flowerheads are long-lasting. It remains a compact shrub.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼

**Ilex aquifolium '*Silver Queen*'**
This slow-growing holly is a reliable performer. It eventually forms a large, cone-shaped shrub with prickly evergreen leaves edged with silver. An undemanding shrub for a dark corner or shaded border, it is a male plant and will not produce berries.

**H**: 40 ft (12 m), **S**: 10 ft (3 m) or more
❄❄❄ ◊ ◑ ☼ ◑

**Lonicera periclymenum '*Graham Thomas*'**
This is one of the best honeysuckles. It is shade-tolerant, free-flowering, and well scented, especially in the evening. Creamy yellow, tubular flowers appear in early summer and throughout the season.

**H**: 12 ft (4 m), **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼ ◑

**Phyllostachys**
Beloved of garden designers, this bamboo is an excellent, well-behaved, clump-forming plant. *P. nigra* has rich ebony stems that contrast well with the bright green foliage. Remove lower branchlets and older stems to show off the color of the stems.

**H**: 22 ft (7 m), **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Sambucus racemosa '*Plumosa Aurea*'**
In spring and summer, this deciduous shrub is furnished with delicate, gold feathery foliage; the young shoots are tinged bronze. It is best if the stems are cut down annually to about 24 in (60 cm) in early spring.

**H**: 10 ft (3 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ◑

**Stewartia monadelpha**
Stewartias are deciduous trees, often developing mottled trunks and impressive autumnal tints before leaf fall. This species is one of the more widely available, producing white summer flowers like those of a small camellia. Grow it in a sheltered spot.

**H**: 70 ft (20 m), **S**: 15 ft (5 m)
❄❄❄ ◑ ☼ ◑

# Medium-sized plants for sun (Ac–Co)

**Acanthus mollis**
With mounds of glossy architectural foliage and handsome prickly spires of purple flowers, this perennial will add a touch of drama to any garden. The large, rich green leaves that emerge in early spring may be damaged by frost.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄ ☼ ☀

**Allium hollandicum '*Purple Sensation*'**
This bulb flowers after the spring bulbs but before summer flowers get going. Rounded, metallic purple flowerheads are carried on tall, slender stems that punctuate lower plantings. Plant in drifts in spring.

**H**: 4 ft (1.2 m), **S**: 8 in (20 cm)
❄❄❄ ☼

**Angelica archangelica**
This herbaceous plant flowers, sets seed, and dies in two years. In its first year, it produces unremarkable clumps of large, divided leaves, but in the second year, it is transformed. A thick stem is topped by soccer-ball-sized heads of bright green flowers.

**H**: 8 ft (2.5 m), **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼ ☀

**Aster turbinellus**
Reaching its best in early fall, this aster has mauve daisy flowers held aloft on slender stems. The yellow-centered blooms are produced in profusion, creating a dainty effect. The stems may need extra support; position any canes or twigs early.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼

**Berberis thunbergii *f.* atropurpurea '*Dart's Red Lady*'**
Berberis are tough and easy to grow, but some make first-rate flowering or foliage plants. This deciduous cultivar with viciously spiny stems is grown for its richly colored red leaves, making a good foil for other garden plants.

**H**: 4 ft (1.2 m), **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ☀

**Bupleurum fruticosum**
This is a fine shrub for a sunny spot, forming a mound of silver-green evergreen foliage, and producing delicate heads of tiny, bright yellow flowers all summer. It thrives in dry, chalky soil and also in the open in mild coastal areas.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄ ☼

**Buxus sempervirens**
Boxwood has a long history in cultivation, thanks to its evergreen nature and responsiveness to clipping. Use as topiary, a low hedge, or shape it to add formality. 'Marginata' (pictured) has yellow-edged leaves. Dislikes waterlogged soil.

**H**: 10–12 ft (3–4 m) if unclipped, **S**: 6 ft (2 m) ❄❄❄ 💧 ◑ ☼ ☀

**Canna '*Striata*'**
Thanks to their exotic flowers and bold foliage, cannas make great plants for a sunny garden. 'Striata' has yellow-striped green leaves and orange flowers in summer. Lift the rhizomes and keep frost-free, or protect with a thick mulch in winter.

**H**: 6 ft (2 m), **S**: 3 ft (1 m)
❄ ◑ ☼

**Chimonanthus praecox**
In summer, this deciduous shrub is unremarkable; in winter, small rounded buds swell and open to waxy, creamy yellow, bell-shaped flowers with a purple center. Their spicy perfume gives the plant its common name of wintersweet.

**H**: 10 ft (3 m), **S**: 6 ft (2 m)
❄❄❄ 💧 ☼

**Choisya ternata *Sundance***
This neat shrub is popular due to its golden evergreen foliage, which is lightly aromatic, as are the sprays of white flowers. It is best grown in some shade, where it becomes lime green and has an illuminating presence. Dislikes waterlogged soil.

**H**: 6 ft (2 m), **S**: 5 ft (1.5 m)
❄❄ 💧 ☼ ☀

**Cistus *x* hybridus**
This easy, evergreen shrub is a sight to behold in early summer. For two to three weeks, it is smothered in masses of single, white flowers with a yellow eye. Cistus are not long-lived, but they will endure drought for a while.

**H**: 4 ft (1.2 m), **S**: 5 ft (1.5 m)
❄❄ 💧 ☼

**Correa '*Dusky Bells*'**
This charming, winter-flowering plant is worth growing in a sheltered, sunny position. Low and shrubby, it has small, evergreen leaves and bears pinkish-red, bell-shaped flowers with protruding anthers in mild spells during winter. It needs shelter.

**H**: 3 ft (1 m), **S**: 24 in (60 cm)
❄❄ 💧 ◑ ☼

# Medium-sized plants for sun (Cr–Hi)

**Crocosmia *x* crocosmiiflora '*Venus*'**
The common montbretia has strappy leaves topped by sprays of orange flowers in late summer, but there are many rather more desirable selections. *C.* x *crocosmiiflora* 'Venus', with gold and red flowers, is a good example.

**H**: 20 in (50 cm), **S**: 24 in (60 cm)
❄❄ 💧 ◑ ☼ ◑

**Dahlia '*Bishop of Llandaff*'**
This popular old cultivar produces velvety, red, single flowers above purple foliage. It is compact, making it good for the smaller yard, and a fine companion for other late-flowering perennials. Lift the plant in winter and keep the tubers frost-free.

**H**: 4 ft (1.2 m), **S**: 24 in (60 cm)
❄ ◑ ☼

**Deutzia *x* rosea '*Campanulata*'**
This compact, deciduous shrub makes a good undemanding plant for the smaller garden. It has upright, twiggy growth and hairy leaves. The blooms, which are bell-shaped and white with a pink tinge, remain beautiful for several weeks.

**H**: 4 ft (1.2 m), **S**: 4 ft (1.2 m)
❄❄❄ 💧 ◑ ☼ ◑

**Dierama pulcherrimum**
The wand flower or angel's fishing rod is aptly named. In summer, long, arching sprays of large, bell-shaped flowers appear from tufts of tough, strappy, evergreen leaves. Flowers are usually pink but sometimes white or even dark purple.

**H**: 5 ft (1.5 m), **S**: 24 in (60 cm)
❄❄ ◑ ☼

**Echinacea purpurea**
The coneflower is a most appealing herbaceous plant, producing pinky-purple daisylike flowers with a large, dark central cone, tinged orange. The flowers are held on sturdy stems, although sideshoots carry later blooms that appear well into fall.

**H**: 4 ft (1.2 m), **S**: 24 in (60 cm)
❄❄❄ 💧 ☼

**Euphorbia characias**
This evergreen perennial is a superb early summer-flowering plant, with rounded heads of lime green bracts surrounding insignificant flowers. The sea green, lance-shaped leaves are carried on fleshy stems that bleed a milky, toxic sap if cut.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄ 💧 ◑ ☼

**Euphorbia *x* martinii**
This spurge is a good choice, being of compact but upright growth and particularly effective in flower. The green blooms have red centers and appear in spring on tall, rounded, airy heads, carried on purple stems with dark evergreen leaves.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ☼

**Grevillea '*Canberra Gem*'**
For much of the year, this unusual evergreen shrub is quietly attractive, clad in narrow, almost needlelike, bright green leaves. In summer, it is transformed with exotic-looking, pink-red flowers dangling here and there. It needs acidic soil.

**H**: 5 ft (1.5 m), **S**: 5 ft (1.5 m)
❄❄ ◊ ☼

**Hebe '*Midsummer Beauty*'**
The length of its floral display makes this evergreen hebe worthy of space in the garden. In midsummer, long spikes of violet and white flowers are produced. They have a delicate fragrance and continue into fall, even winter, if the weather is mild.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄ ◊ ◑ ☼ ◒

**Helenium '*Moerheim Beauty*'**
This late-flowering border perennial is deservedly popular. From mid- to late summer to early fall, it produces shuttlecock-shaped, daisylike flowers in rich marmalade shades on sturdy, upright stems. Deadheading ensures a later flush of blooms.

**H**: 4½ ft (1.4 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼

**Hemerocallis '*Corky*'**
A clump-forming perennial with narrow, strappy foliage. Slender stems appear in summer, carrying clusters of orange-yellow, funnel-shaped flowers, each displaying a red tinge to the outside. The blooms last just a day but are soon followed by others.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼ ◒

**Hibiscus syriacus '*Oiseau Bleu*'**
Few shrubs better this hibiscus in full bloom. Just as many other plants are fading, it produces a profusion of 3-in- (8-cm-) wide, open bell-shaped flowers of rich blue—a rare color so late in the season. The flowers last until early fall.

**H**: 8 ft (2.5 m), **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

# Medium-sized plants for sun (In–Ph)

**Inula hookeri**
This clump-forming perennial should be more widely grown. It produces beautiful yellow flowers with slender petals that appear from midsummer at the tips of soft stems bearing hairy oval leaves. In late fall, the shoots can be cut to the ground.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Iris laevigata**
This plant is perfect for moist areas, growing well even in standing water. The sword-shaped foliage provides a contrast to other shrubby growth. In early to midsummer, flowering stems bear a succession of beautiful blooms, usually lavender-blue in color.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◑ ● ☼ ◑

**Iris sibirica '*Perry's Blue*'**
Siberian irises are good for ground that does not dry out. In spring, slender, strappy foliage erupts from clumps, followed by tall, branched, flowering stems. These bear dainty sky blue flowers with white markings, 2½ in (6 cm) across, over several weeks.

**H**: 3 ft (1 m), **S**: 20 in (50 cm)
❄❄❄ ◑ ● ☼ ◑

**Lavandula stoechas**
With its aromatic foliage and long-lasting flowers, French lavender lends a Mediterranean feel to sunny gardens. The flowerheads have distinctive purple "ears," or bracts, held on stems above the narrow, grayish-green leaves. Grow in a sheltered spot.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)

**Lilium regale**
This is an easy lily to grow. Fleshy stems furnished with narrow leaves appear in spring and grow rapidly. Large buds swell and burst to reveal silver-white, trumpet-shaped flowers with protruding stamens and a wonderful scent.

**H**: 5 ft (1.5 m), **S**: 12 in (30 cm)
❄❄❄ ◊ ☼ ◑

**Lobelia tupa**
In spring, this exotic-looking plant produces fleshy, red-flushed shoots with large, rather downy leaves. In late summer, heads of red, tubular flowers open over several weeks, and last well into fall. Cut stems to the ground after the first frost.

**H**: 6 ft (2 m), **S**: 3 ft (1 m)
❄❄ ◊ ◑ ☼

**Melianthus major**
A remarkable foliage plant, with dramatic, blue-silver, deeply cut leaves that look superb in a white border or with contrasting purple foliage. Usually it is cut to the ground by frost, and should be covered with a thick mulch to protect the roots.

**H**: 6 ft (2 m), **S**: 3 ft (1 m)
❄❄ ◊ ◑ ☼

**Miscanthus sinensis '*Zebrinus*'**
With its tall stems and strappy foliage, this ornamental grass is a favorite. The leaf blades are marked with broad yellow stripes, giving the plant a remarkable appearance, especially when grown in full sun, which helps intensify the markings.

**H**: 6 ft (2 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼ ◑

**Nandina domestica**
A most useful shrub, this plant checks all the boxes. It has a delicate yet architectural form with large, divided leaves that develop attractive autumnal tints. In early summer, sprays of white flowers appear, followed by clusters of orange berries that persist into winter.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ☼ ◑

**Pennisetum setaceum '*Rubrum*'**
This delightful grass is a tender perennial, ideal for a container in a sunny spot during summer. Best treated as an annual, it will produce purple fluffy flowerheads (known as "cats' tails") held on arching stems, above rich red foliage.

**H**: 3 ft (1 m), **S**: 24 in (60 cm)
❀ ◑ ◊ ☼

**Perovskia '*Blue Spire*'**
This delicate-looking, shrubby plant is a good choice for a sunny, dry position. It forms an upright bush with strongly aromatic, silver-green foliage. From late summer until fall, clouds of violet-blue flowers are produced.

**H**: 4 ft (1.2 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ☼

**Phlomis russeliana**
A dependable, useful perennial with large, soft, heart-shaped leaves that cover the ground well, even in winter. In early summer, attractive stout stems of soft yellow flowers appear. After flowering, these stems provide structure into fall and winter.

**H**: 3 ft (1 m), **S**: 4 ft (1.2 m)
❄❄❄ ◑ ◊ ☼ ◑

# Medium-sized plants for sun (Ph–We)

**Phormium '*Yellow Wave*'**
This tried-and-tested phormium is graceful and compact. Its broad, evergreen, strappy foliage is lavishly marked with yellow, set against green, each blade arching gracefully to give established clumps an elegant appearance.

**H**: 4 ft (1.2 m), **S**: 3 ft (1 m)
❄❄ 💧 ◑ ☼ ◑

**Pinus mugo '*Ophir*'**
This compact, slow-growing pine is ideal for the smaller garden, growing well even in a container. Its short branching stems are covered in dense bristles and it will form a large shrub. However, it is most attractive in winter, when its needles turn bright gold.

**H**: 5 ft (1.5 m), **S**: 5 ft (1.5 m)
❄❄❄ 💧 ☼

**Pittosporum tobira**
With its shiny, evergreen leaves and heads of cream-colored, sweetly scented summer flowers, this plant should be seen more often. It grows throughout the Mediterranean, so is a good choice for those who like to be reminded of warmer climes.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄ 💧 ☼

**Rosa *x* odorata '*Mutabilis*'**
A most beautiful rose that flowers from late spring until late fall. Clusters of dainty, single flowers open a warm orange-yellow and turn rich pink with age. The young stems and leaves of this compact, but open, bush are tinged purple.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄ 💧 ☼

**Rosa xanthina '*Canary Bird*'**
This rose is one of the earliest to bloom—in late spring. It produces a profusion of single, sunshine yellow flowers, which have a light perfume, and has attractive apple green foliage. A second reduced display appears in fall.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ 💧 ☼

**Rosmarinus officinalis**
This dense evergreen has strongly aromatic foliage and attractive blue flowers in spring and sometimes fall. It will grow well in pots, is drought-tolerant, and responds well to trimming. It is a useful herb for cooking.

**H**: 5 ft (1.5 m), **S**: 5 ft (1.5 m)
❄❄ 💧 ☼

**Salvia officinalis '*Purpurascens*'**
Purple sage is a useful plant for the smaller garden: it is easy, quick-growing, and has aromatic, oval, soft, purple leaves. The plant forms ground-covering mounds, and in summer sends up flowering stems with small purple blooms.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄ ☼

**Salvia *x* sylvestris '*Mainacht*'**
Many salvias are first-rate plants for their summer flowers; this compact selection is useful in the smaller plot. Its early summer flowers are of an intense purplish-blue that is unusual for the time of year. They are carried in profusion in stiff upright spikes.

**H**: 3 ft (1 m), **S**: 20 in (50 cm)
❄❄ ☼

**Stipa gigantea**
The perennial giant oat, although large, is manageable in almost any garden. It forms a low hummock of long, narrow leaves, and in summer, produces tall stems bearing transparent golden flowerheads that shimmer in the breeze.

**H**: 6 ft (2 m), **S**: 3 ft (1 m)
❄❄❄ ☼ ◑

**Trachycarpus wagnerianus**
This is the perfect hardy palm for smaller yards, as it is slow-growing and compact. The plant forms a trunk gradually and is furnished with fan-shaped, dark, evergreen, deeply pleated leaves that give it a most refined appearance.

**H**: 6 ft (2 m) after 10 years, **S**: 6 ft (2 m)
❄❄❄ ☼ ◑ ☼ ◐

**Verbena bonariensis**
This "must-have" perennial is a useful plant even in small gardens because, although tall, it has a transparent quality, allowing views of plantings behind it. It is long-flowering, with heads of purple blooms appearing in summer and lasting into fall.

**H**: 6 ft (2 m), **S**: 24 in (60 cm)
❄❄ ☼

**Weigela '*Eva Rathke*'**
These shrubs are grown for their spring and early summer blossoms. This compact selection forms a dense shrub. Dark red flower buds appear in profusion in late spring and open to crimson, funnel-shaped flowers. Remove oldest stems after flowering.

**H**: 5 ft (1.5 m), **S**: 5 ft (1.5 m)
❄❄❄ ☼ ◐

# Medium-sized plants for shade (Ac–De)

**Acer shirasawanum '*Aureum*'**
This slow-growing, compact plant is striking, especially in late spring and early summer when its foliage is at its best. As the golden leaves expand, they resemble little Chinese fans, seen to best effect in shade where they stand out from other plantings.

**H**: 5 ft (1.5 m) after 10 years, **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼

**Anemanthele lessoniana**
This grass is better known as *Stipa arundinacea*. It makes a neat clump of fairly broad, evergreen foliage, the leaves arching attractively. In late summer, tiny flowers are produced. In fall, the clump develops russet tints, adding to its desirability.

**H**: 4 ft (1.2 m), **S**: 4 ft (1.2 m)
❄❄ ◊ ☼ ◑

**Anemone *x* hybrida '*Honorine Jobert*'**
There are few perennials to match this noble plant in late summer. Vigorous clumps of bold, divided foliage build up steam through the summer until flowering stems appear, topped by sprays of single, white flowers.

**H**: 5 ft (1.5 m), **S**: 24 in (60 cm)
❄❄❄ ◑ ◑

**Aquilegia *McKana Group***
A cottage-garden favorite, this perennial is a good choice for its spring flowers in a wide range of different colors. The clumps of foliage develop in spring and are soon topped by distinctive flowers lasting for several weeks.

**H**: 3 ft (1 m), **S**: 20 in (50 cm)
❄❄❄ ◊ ☼ ◑

**Aruncus dioicus**
This large but easy-to-grow perennial is suited to moist sites. In spring, shoots soon form hummocks of leafy stems. By midsummer, plumes of tiny creamy white flowers appear. They are held in handsome flowerheads and last for several weeks.

**H**: 6 ft (2 m), **S**: 4 ft (1.2 m)
❄❄❄ ◑ ● ☼ ◑

**Astilboides tabularis**
A plant of great beauty, this species' main feature is its large, parasol-like leaves, each roughly circular, with the leaf stem attached to the center. Soft green and delicate in early summer, they darken as the season progresses. White flowers appear in late summer.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ● ◑

**Aucuba japonica**
This evergreen deserves recognition as one of the best shrubs for year-round appeal. It will also withstand mistreatment. Its large oval leaves are spangled with golden spots. In spring, heads of red-purple flowers appear and develop into crimson berries.

**H**: 8 ft (2.5 m), **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ● ◑

**Berberis darwinii**
This spiny evergreen is one of the most spectacular spring-flowering shrubs and deserves a spot at the back of a border. The glossy foliage is an attractive foil to the clusters of bright orange flowers that cover the plant, followed later by blue berries.

**H**: 6 ft (2 m) after 10 years, **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ◑

**Camellia japonica '*Bob's Tinsie*'**
This plant is a favorite, thanks to its unusual flowers and neat, compact habit. The glossy, oval, evergreen foliage is a good foil to the small, cup-shaped, red flowers that appear in abundance throughout spring.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ◑

**Cornus sanguinea '*Winter Beauty*'**
This shrub is grown for the color of its twigs. In summer, it is forgettable, but once the leaves turn butter yellow in fall, the show begins. The stems are bright orange-yellow, the younger shoots tinged red, making the plant look like a glowing flame.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ◑

**Cotoneaster horizontalis**
This shrub has much to recommend it. In spring, the soft green foliage is the attraction, followed by pink-white flowers in summer. In fall, the leaves turn crimson before they drop; in winter, the stems are often peppered with red berries.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ◑

**Desfontainia spinosa**
At first glance, this plant resembles a compact holly with its small, dark, spine-edged leaves. In summer, it has a trick up its sleeve: long, tubular, pendent, red and yellow flowers appear, and are of great beauty, especially against the dark foliage.

**H**: 3 ft (1 m), **S**: 24 in (60 cm)
❄❄ ◑ ◑

# Medium-sized plants for shade (Di–Le)

**Dicentra spectabilis**
The bleeding heart is a popular plant for light shade. Fleshy shoots emerge as winter ends and are easily damaged by late frosts. The soft foliage, which dies down in midsummer, is topped by arching sprays of pink and white flowers that last for several weeks.

**H**: 3 ft (1 m), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Digitalis purpurea**
The foxglove is easy to grow, thrives in shade, and seeds freely. It is usually a biennial, which means it lives for two years, building up a rosette of large oval leaves in the first, and producing its tall flower spike in the second. The flowers are usually purple or white.

**H**: 6 ft (2 m), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ☼

**Geranium *x* oxonianum '*Claridge Druce*'**
This herbaceous plant is one of the toughest, and ideal for dry shade. It develops a mound of foliage that is often semievergreen, above which appear bright pink flowers from spring until late fall.

**H**: 4 ft (1.2 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ● ☼ ☼

**Hedychium densiflorum**
This hardy ginger makes a fine late-flowering perennial. In summer, it develops vigorous, fleshy shoots that grow quickly and display lush foliage. At the tips of each shoot appear spikes of scented, orange flowers that are produced well into fall.

**H**: 4 ft (1.2 m), **S**: 6 ft (2 m)
❄❄ ◊ ◑ ☼ ☼

**Helleborus argutifolius**
This evergreen perennial is a useful plant, growing well in shade and filling gaps with its handsome serrated foliage, held on rather shrubby stems. In winter, bright green, open flowers appear. After flowering, stems wither and yellow and should be cut out.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄ ◊ ◑ ☼ ☼

**Hosta '*Jade Cascade*'**
This huge, sturdy yet elegant hosta is well named. The long, pointed, rich green leaves, up to 12 in (30 cm) long, are strongly veined and held in a distinctive, downward-facing way on tall leaf stems. In early summer, tall spires of lilac blooms appear.

**H**: 4 ft (1.2 m), **S**: 3½ ft (1.1 m)
❄❄❄ ◑ ☼

**Hosta sieboldiana**
This large hosta has fine foliage. The leaves, which emerge from blue, toothlike shoots in spring, are blue-gray at first, developing a green tinge as they age. Mature clumps make large mounds of puckered leaves 12 in (30 cm) long and the same across.

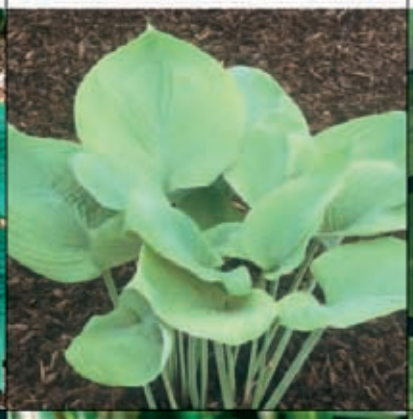
**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼

**Hosta '*Sum and Substance*'**
A spectacular hosta cultivar that is one of the largest and easiest to grow of all, with huge golden-green leaves, especially bright as they first emerge in spring. In summer, tall spikes of lavender flowers appear. This hosta is also relatively slug-resistant.

**H**: 30 in (75 cm), **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼

**Hydrangea macrophylla '*Lanarth White*'**
This hydrangea forms a rounded dome of growth. The flattened heads are composed of tiny blue or pink fertile flowers surrounded by pure white florets, and appear in late summer. The flowers show up best in shade.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼



**Ilex crenata *var.* latifolia**
This holly looks rather like boxwood, but it is quicker-growing. It responds well to trimming and can be kept as a low hedge. Other selections include *I. crenata* 'Golden Gem', which has glowing yellow foliage and makes a superb plant for shade.

**H**: up to 5 ft (1.5 m), **S**: 5 ft (1.5 m)
❄❄❄ ◊ ◑ ☼ ☼

**Iris foetidissima**
This perennial is great for shade, even under trees and shrubs. The lance-shaped foliage remains in good condition in winter, and in spring, purple flowers appear. The orange seeds, which remain showy all winter, are the main talking point.

**H**: 3 ft (1 m), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Leucothoe fontanesiana '*Rainbow*'**
A clump-forming evergreen shrub with an attractive, arching, fountain-shaped habit. The leaves are splashed and flecked with cream, pink, and orange. In summer, white, bell-shaped flowers hang from the stems.

**H**: 5 ft (1.5 m), **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼

# Medium-sized plants for shade (Le–Vi)

**Leycesteria formosa**
An excellent shrub for a range of situations, including dry shade. In summer, clusters of pinky-purple flowers hang from arching stems amid lush oval leaves. By fall, purple berries develop. The green stems are attractive in winter.

**H**: 5 ft (1.5 m), **S**: 4 ft (1.2 m)
❄❄❄ ◊ ◑ ☼ ☼

**Ligularia dentata '*Desdemona*'**
This leafy perennial is a dramatic choice for moist sites. Clumps of large, rounded leaves flushed with purple are held on long stems, which appear from the ground in spring. These are followed by tall stems with orange-yellow, daisylike flowers.

**H**: 4 ft (1.2 m), **S**: 24 in (60 cm)
❄❄❄ ◑ ● ☼

**Osmunda regalis**
A large, deciduous fern, ideal for moist areas. In spring, croziers unwind from the ground and fresh, bright green fronds unfurl. Clumps provide an architectural element in summer; in fall, they turn bright yellow.

**H**: 4 ft (1.2 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ● ☼

**Pieris '*Forest Flame*'**
This evergreen shrub is grown for its dramatic, bright red shoots and sprays of white, bell-shaped flowers. The flowers appear in early spring before the scarlet shoots. As the leaves mature, they fade to pink before turning green. It needs acidic soil.

**H**: 8 ft (2.5 m), **S**: 6 ft (2 m)
❄❄❄ ◑ ☼

**Primula florindae**
The largest and most spectacular of primulas, this perennial resembles a giant cowslip. Clumps of broad, soft green leaves 12 in (30 cm) long develop in spring, followed by tall flower stems that carry scented, bell-shaped flowers in yellow or orange.

**H**: 4 ft (1.2 m), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Rhododendron '*Olive*'**
This evergreen rhododendron needs a sheltered position and acidic soil to do well. The small, green, oval leaves serve as a good foil to the clusters of bright mauve-pink, funnel-shaped flowers up to 1½ in (4 cm) across. These are produced in late winter.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼

**Rhododendron '*Persil*'**
This plant is a wonderful sight in late spring. Heads of large, scented, white flowers with a yellow flash in the center appear at the same time as the soft, hairy leaves. The flowers last for several weeks, and show up well in shade. The plant needs acidic soil.

**H**: up to 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ◑

**Ribes sanguineum '*Brocklebankii*'**
This compact flowering currant is most attractive in spring, the pink flowers appearing at the same time as the yellow leaves—to spectacular effect. This plant shows up well in shade and grows better out of sun because the leaves can scorch.

**H**: 5 ft (1.5 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑

**Sarcococca hookeriana *var.* digyna**
Evergreen, compact, and winter flowering, this shade-loving plant is ideal for small gardens. The narrow leaves are shiny and the plant forms a dense, rounded mound. In winter, small, white tassels appear: these have a delicious, spicy scent.

**H**: 3 ft (1 m), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ◑

**Skimmia *x* confusa '*Kew Green*'**
With its glossy, pointed leaves, this skimmia cultivar is one of the most reliable. The large, conical, greenish-cream flowerheads, produced in early spring, have a delicious scent. This is a male plant; for berries, a female or hermaphrodite plant is required.

**H**: 3 ft (1 m), **S**: 5 ft (1.5 m)
❄❄❄ ◑ ◑

**Viburnum davidii**
This evergreen shrub, which forms a low mound, is a plant for all seasons. The oval leaves are attractively pleated and rich green. In summer, large heads of small, white flowers appear. Bright blue berries follow, provided male and female plants are grown.

**H**: 3 ft (1 m), **S**: 6 ft (2 m)
❄❄ ◊ ◑ ◑

**Viburnum tinus '*Eve Price*'**
A compact and free-flowering evergreen plant that makes an ideal backdrop at the back of a border. It forms dense cover and has small, green, oval leaves. Heads of pink-tinged flowers are displayed through winter and spring.

**H**: 6 ft (2 m), **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ◑

# Short plants for sun (Al–Di)

**Allium schoenoprasum**
Chives are not only useful in an herb garden—they are also an easy-to-grow choice for a flower garden and ideal as border edging. The narrow, blue-green leaves are especially attractive when topped by pinkish-mauve flowers that last several weeks.

**H**: 12 in (30 cm), **S**: 8 in (20 cm)
❄❄❄ ◊ ☼

**Artemisia alba '*Canescens*'**
This useful front-of-border perennial, with its silver leaves, should be more widely grown. The lacy foliage is held on stems that tend to sprawl, covering the soil well. Cut plants to the ground in a cold winter, and new shoots will appear in spring.

**H**: 12 in (30 cm), **S**: 12 in (30 cm)
❄❄ ◊ ☼

**Aster '*Coombe Fishacre*'**
In early fall, few plants can compete with asters. This selection has a long flowering period and is well suited to smaller gardens. The blooms are daisylike, pink with a darker eye, and appear in a multitude, lasting until the first frost.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ☼

**Astrantia major**
These beautiful perennials are becoming popular, thanks to the range now available. Clumps of leaves appear in spring and are topped by dainty flowers held on tall stems. The showy white or pink bracts resemble petals and encircle the true flowers.

**H**: 18 in (45 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ☼ ◑

**Bergenia purpurascens**
This perennial has beautiful foliage and flowers. It is more compact and has a longer season of interest than most bergenias, so it is better suited to small gardens. The glossy foliage develops rich purple tints in winter; in spring, pinkish-purple flowers appear.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ☼ ◑

**Calluna vulgaris '*Silver Knight*'**
For silver foliage, few heathers create a better effect than this shrubby, evergreen plant. When mature, it produces a wonderful wispy silver cloud of dense, quite upright, but ground-covering, growth. Although easy to grow, it must have acidic soil.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Campanula glomerata**
One of the simplest campanulas to grow, this low, spreading perennial makes a good summer ground cover, and self-seeds freely. From early summer until fall, heads of bell-shaped blue or white flowers appear on short stems.

**H**: 12 in (30 cm), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼ ☼

**Catananche caerulea**
This sun-loving perennial is grown for its lavender-blue flowers, which look rather like pale cornflowers, produced in summer and fall. The blooms are held on a wiry stalk above clumps of silvery foliage. They combine well with other pale-colored plants.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄ ◊ ☼

**Ceratostigma plumbaginoides**
Easy to grow, this low shrub flowers when most other plants have finished. It spreads at the root and, under ideal conditions, forms a large clump. The rich blue flowers are held in clusters above the leaves, which turn red before falling.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼

**Cerinthe major**
Growing swiftly from seed, this annual develops into a low bush, covered in blue-silver leaves. Long-lasting, purple, bell-shaped flowers appear in late spring, giving an attractive, almost iridescent appearance. It self-seeds freely.

**H**: 18 in (45 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ☼

**Convolvulus cneorum**
This evergreen, low-growing shrub is grown for both its soft, bright silver foliage and the multitude of white, cup-shaped flowers that appear in summer. Each flower lasts little more than a day, but the bush is covered in blooms for weeks.

**H**: 20 in (50 cm), **S**: 3 ft (1 m)
❄❄ ◊ ☼

**Diascia barberae '*Blackthorn Apricot*'**
Often grown as an annual, this plant is perennial in the right position. Although cut to the ground in winter, new stems appear in spring to make a small sprawling clump. The stems bear peach-colored flowers all summer.

**H**: 12 in (30 cm), **S**: 12 in (30 cm)
❄❄ ◊ ☼

# Short plants for sun (Er–Ge)

**Erica carnea '*Foxhollow*'**
There are many winter-flowering heathers, but this is a favorite, bearing small, pale pink, bell-shaped flowers throughout the coldest weather. The needlelike, pale green leaves become tinged with red in winter. A good low-growing plant.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Erigeron karvinskianus**
The little Mexican daisy is a welcome plant in many gardens, often growing in gaps in paving or out of dry stone walls—anywhere hot and dry. The small pink-tinged white daisy flowers appear from early summer to winter on low, sprawling plants.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼

**Erysimum '*Bowles' Mauve*'**
This is a superb plant for injecting color into cottage-garden-style plantings in spring and summer. It forms an evergreen, shrubby plant with gray-green leaves. In spring, the flowering stems are soon covered with purple flowers.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼

**Euphorbia cyparissias '*Fens Ruby*'**
This low-growing perennial is a useful, if somewhat invasive, plant, grown for its foliage and spring flowers. In spring, purplish-green shoots appear, producing delicate foliage. As the season progresses, small, lime green flowers develop.

**H**: 12 in (30 cm), **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼

**Euphorbia rigida**
This sprawling plant is superb in a sunny rock garden. Fleshy stems arise from a central crown, then grow along the ground in an almost snakelike fashion, holding narrow, triangular blue-silver leaves. Lime green flowers appear in early summer.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼

**Francoa sonchifolia**
In a sunny, warm area, this perennial makes a good ground cover. The fleshy leaves grow from a creeping stem, which in mid- to late summer sends up tall stems, well above the foliage, of pale pink flowers spotted with darker pink.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼ ◑

**Fuchsia '*Genii*'**
This compact, hardy fuchsia is a reliable cultivar. It produces masses of pendent purple and red flowers in late summer and fall, until the first frost. The blooms are held against bright yellow leaves, adding to the plant's impact.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄ ☼ ◑

**Gaura lindheimeri**
A delicate-looking perennial for the front of a sunny border that produces wands of open, white flowers held on slim stems from midsummer until mid-fall. A hard frost will kill the top growth, but fresh shoots appear in spring if protected in winter.

**H**: up to 3 ft (1 m), **S**: 3 ft (1 m)
❄❄ ☼

**Geranium '*Ann Folkard*'**
This hardy geranium is appealing for both flowers and foliage. The leaves are hand-shaped and bright gold in color, especially when young; they become greener as they age. Large, open, bright magenta flowers with dark centers are produced all summer.

**H**: 24 in (60 cm), **S**: 3 ft (1 m)
❄❄❄ ☼ ◑

**Geranium *Rozanne* ('*Gerwat*')**
One of the finest of all cranesbills, this selection has trailing, non-rooting stems that cover the ground from late spring, producing masses of large, open, bright blue flowers from early summer well into fall. Cut back stems in winter.

**H**: 18 in (45 cm), **S**: 24 in (60 cm)
❄❄❄ ☼ ◑

**Geum coccineum**
This clump-forming perennial is a fine summer-flowering plant. It forms a rosette of toothed green leaves, and attractive, open, saucer-shaped, orange-red flowers with yellow stamens for several weeks. Plants like sun but not overly dry soil.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◑ ● ☼ ◑

**Geum rivale**
A European native, the little water avens is attractive for wet areas, perhaps in wilder patches of the garden. This perennial forms clumps of leaves, and over several weeks in early summer produces dusky pink and red bell-shaped flowers.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◑ ● ☼

# Short plants for sun (Ha–Pe)

**Hakonechloa macra '*Aureola*'**
This ornamental grass is a fine garden plant. It forms a low clump of gold and green striped foliage. The plant spreads slowly from slender rhizomes and will grow in a range of situations, including sun, as long as the soil is moist.

**H**: 12 in (30 cm), **S**: 16 in (40 cm)
❄❄❄ 💧 ◑ ☼ ☼ ☀

**Helianthemum '*Rhodanthe Carneum*' ('*Wisley Pink*')**
This low-growing plant is ideal for sunny rock gardens. Plants are evergreen with small, oval, silvery foliage. In early summer, silver-pink flowers with a soft yellow eye appear. They last a day, but are produced in profusion.

**H**: 12 in (30 cm), **S**: 20 in (50 cm)
❄❄❄ 💧 ☼

**Hemerocallis '*Golden Chimes*'**
A dainty day lily, ideal for the small garden because it is compact and free-flowering. In summer, flowering stems appear from clumps of narrow, arching leaves. The bright yellow, open, trumpet-shaped flowers have brownish-red reverses.

**H**: up to 3 ft (1 m), **S**: 20 in (50 cm)
❄❄❄ 💧 ☼ ◑

**Hypericum olympicum**
An ideal plant for open, sunny positions, this low-growing shrub is a fine sight in summer. The small leaves are gray-green and a good foil to the open, starry, golden yellow flowers produced in clusters at the ends of the stems.

**H**: 12 in (30 cm), **S**: 20 in (50 cm)
❄❄❄ 💧 ☼

**Iris unguicularis**
Few herbaceous plants are of interest in winter, but this evergreen iris is a stellar performer. For much of the year, it is unremarkable, but in mild spells during winter, delicate lavender-mauve flowers with yellow markings open, lasting several days.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ 💧 ☼

**Lychnis flos-cuculi**
The ragged robin is a European native. It is a short-lived perennial that sends up tall flowering stems in early summer. The flowers are open, starry, usually pale pink, sometimes white, with long narrow petals. Plants grow well in damp shade.

**H**: 30 in (75 cm), **S**: 12 in (30 cm)
❄❄❄ 💧 ◑ ☼ ◑

**Narcissus '*Jetfire*'**
There are many narcissi to choose from, but this selection, with its elegant and brightly colored early spring blooms, is a favorite. The flower petals are rich gold and reflexed, while the trumpet is a contrasting reddish orange.

**H**: 9 in (22 cm), **S**: 4 in (10 cm)
❄❄❄ ◊ ☼ ◑

**Nepeta *x* faassenii**
Useful and easy, catmint is a clump-forming plant with spreading stems and blue-green, soft, aromatic foliage that is attractive to cats. In summer, sprays of blue flowers appear. If the plant is cut back after flowering, it will produce a second crop.

**H**: 20 in (50 cm), **S**: 20 in (50 cm)
❄❄❄ ◊ ☼

**Oenothera speciosa**
Low-growing and sun-loving, this plant spreads freely at the root, especially in light soil, producing short, upright stems. The large, cup-shaped, pink flowers open from pointed buds and are short-lived, but appear in great profusion throughout summer.

**H**: 12 in (30 cm), **S**: 20 in (50 cm)
❄❄❄ ◊ ☼

**Osteospermum '*Sunny Serena*'**
A tender perennial, grown for its dazzling daisy flowers in summer and well into fall, this plant is well suited to container cultivation or filling gaps in sunny beds and borders. Remove blooms as they fade and fertilize regularly if in a pot.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄ ◊ ☼

**Penstemon '*Alice Hindley*'**
With its shimmering, pale mauve-violet flowers carried in upright flowerheads, this is one of the most desirable penstemons. Oval leaves are carried on woody stems that should not be cut back until spring, when new shoots arise from the base of the plant.

**H**: 30 in (75 cm), **S**: 20 in (50 cm)
❄❄ ◊ ☼

**Penstemon '*Andenken an Friedrich Hahn*'**
A most popular penstemon, this plant is better known as *P.* 'Garnet'. Loose but upright flowerheads of rich red, tubular blooms appear throughout summer and well into fall, until the first frost.

**H**: 30 in (75 cm), **S**: 24 in (60 cm)
❄❄ ◊ ☼

# Short plants for sun (Pe–Za)

**Persicaria affinis '*Superba*'**
For ground cover, there are few plants to match this perennial, particularly in late summer and fall, when the blooms open pale pink and age to crimson, giving a fine two-tone look on the same plant. Rust-brown leaves carpet the ground in winter.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◑ ◊ ☼ ☀

**Phlox '*Chattahoochee*'**
A low-growing perennial that is ideal for the front of a border or a rock garden. In early summer, flowers are carried in clusters. They are a delightful rich lilac color with a central reddish-purple eye, and are produced in profusion.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ☼ ☀

**Pittosporum tenuifolium '*Tom Thumb*'**
This evergreen makes a great addition to the smaller garden, with its compact form and mahogany-colored foliage. The leaves are particularly attractive in spring as green new growth emerges, giving the plant a two-tone effect.

**H**: up to 3 ft (1 m), **S**: 24 in (60 cm)
❄❄ ◊ ☼

**Pulsatilla vulgaris**
The pasque flower is one of the most beautiful spring flowers. The fernlike foliage forms a small clump, while its star-shaped flowers are usually rich purple, but can be pink, red, or white, and have a boss of golden stamens. The plant prefers chalky soil.

**H**: 12 in (30 cm), **S**: 8 in (20 cm)
❄❄❄ ◊ ☼

**Rudbeckia fulgida *var.* sullivantii '*Goldsturm*'**
Perennials that flower in fall are valuable, and this plant is also compact. Its daisylike flowers, with narrow, golden petals and a black central cone, open atop sturdy stems, which should be cut to the ground after flowering.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Sedum '*Herbstfreude*'**
With its succulent gray-green stems and foliage, this plant is well adapted to withstand hot sun and drought. In late summer, flat heads of rust red flowers open, lasting for several weeks; the dry flowerheads remain attractive into winter.

**H**: 24 in (60 cm), **S**: 3 ft (1 m)
❄❄❄ ◊ ☼

**Sisyrinchium striatum '*Aunt May*'**
This choice plant earns its keep. All year, the rapier-like foliage, striped lengthwise with cream and gray-green, provides striking contrast to more rounded shapes. In early summer, spikes of primrose yellow flowers open in succession.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄ 💧 ☼

**Stachys byzantina '*Big Ears*'**
This selection of the common lambs' ears has large, oval leaves, which are covered with silvery white "wool." The low-growing plant is particularly attractive at the front of a pale-colored border. In summer, erect spikes of mauve flowers appear.

**H**: 24 in (60 cm), **S**: 3 ft (1 m)
❄❄❄ 💧 ☼

**Stipa tenuissima**
This perennial grass is a good choice for the garden, since it is beautiful for much of the year. In spring, the bright green growth is attractive, but in summer, the flowerheads give clumps a fluffy appearance, and as the seeds form, plants become straw-colored.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄ 💧 ☼

**Veronica gentianoides '*Tissington White*'**
A good plant for early summer, this low-growing perennial carpets the ground with its shiny oval leaves. Numerous spikes of gray-white flowers arise in late spring and remain attractive for several weeks.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄❄ 💧 ◑ ☼

**Vinca difformis**
Periwinkles are popular ground-covering plants, but this species is more refined than many. The flowers are its main attraction. They are produced through much of winter and spring and are pale blue to nearly white and propeller-shaped.

**H**: 24 in (60 cm), **S**: 4 ft (1.2 m)
❄❄ 💧 ☼ ◑

**Zauschneria californica**
Spectacular in flower, this plant needs a hot situation to grow well, but is an excellent choice for a sunny corner. It forms a low plant with small gray-green leaves. In late summer, sprays of vibrant, orange-red flowers appear, each bloom shaped like a small fuchsia.

**H**: 24 in (60 cm), **S**: 24 in (60 cm)
❄❄ 💧 ☼

# Short plants for shade (Al–He)

**Alchemilla mollis**
Commonly known as lady's mantle, this perennial thrives in the shade. The soft green leaves form a mound of growth, and have a charming way of catching water droplets. In summer, heads of lime green, small flowers appear.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Arum italicum *subsp.* italicum '*Marmoratum*'**
This perennial is grown for its winter foliage. Leathery leaves, richly veined in silver-white, appear in late fall. The green flowers in summer are unremarkable, but later displays of red berries (poisonous) are attractive.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Brunnera macrophylla '*Dawson's White*'**
This compact perennial needs a cool, moist position. The hairy, heart-shaped leaves, margined with white, are particularly attractive with the sprays of blue flowers that are carried on stems above the foliage.

**H**: 12 in (30 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Carex elata '*Aurea*'**
With vibrant fountains of rich, golden, grassy foliage, this clump-forming deciduous perennial is a desirable plant for moist, even wet, soil in shade. Here, it shines out from darker plants, especially in spring when the leaves are young.

**H**: 28 in (70 cm), **S**: 18 in (45 cm)
❄❄❄ ◑ ● ☼

**Cornus canadensis**
A seldom-seen ground-cover plant that spreads by rhizomes in acidic soil. The leaves are held around short stems, and showy white flowerheads are borne in early summer. Each has four "petals" that are actually bracts, and may be followed by red berries.

**H**: 8 in (20 cm), **S**: 3 ft (1 m)
❄❄❄ ◑ ☼

**Corydalis flexuosa**
This dainty perennial is easy to grow in a cool corner. It comes into growth early, fleshy shoots producing fern-like leaves. The electric blue flowers are held in clusters and look rather like shoals of little fish. After flowering, plants often die down quickly.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Cyclamen hederifolium**
This is an essential plant for its fall flower displays. The plant grows from a corm just below the surface of the soil, sending up masses of pink or white flowers, followed by attractive leaves that are marked with silver or darker green.

**H**: 4 in (10 cm), **S**: 8 in (20 cm)
❄❄❄ ◊ ◑ ☼

**Daphne laureola *subsp.* philippi**
This upright bushy evergreen is slow-growing and suited to the smaller yard. The leaves are shiny and clustered toward the tops of the stems, from where, in late winter, strongly perfumed, green bell-shaped flowers appear, followed by black berries.

**H**: 24 in (60 cm), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼

**Epimedium *x* versicolor**
These easy-to-grow, clump-forming perennials are good for shaded spots under shrubs. The dainty, divided foliage is attractive, especially in spring, and is often bronze-tinged. Clusters of yellow, orange, or pink flowers appear at the same time.

**H**: 8 in (20 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Galanthus nivalis**
The first flowers of the common snowdrop are a sign to gardeners that spring is on the way. These plants grow well in shade and will quickly bulk up to form large clumps, which need to be split regularly to keep them flowering.

**H**: 4 in (10 cm), **S**: 8 in (20 cm)
❄❄❄ ◊ ◑ ☼

**Geranium macrorrhizum**
This is one of the lower-growing cranesbills, good for planting under larger shrubs and forming a dense ground cover with its soft aromatic foliage. In spring, short stems produce clusters of pink, mauve, or white flowers over several weeks.

**H**: 12 in (30 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Helleborus *x* hybridus**
Also known as Lenten roses, these perennials are very popular spring plants. In late winter, new shoots emerge; the nodding flowers appear first, followed by the leaves. The flowers come in many colors (but not blue), and they last for weeks.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

# Short plants for shade (He–Uv)

**Heuchera '*Plum Pudding*'**
This foliage plant makes an attractive addition to a shady border. The rounded, evergreen, wavy-edged leaves are purple-red with silver markings that give the plant a metallic shimmer. In summer, spires of flowers are held above the foliage.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Lysimachia nummularia '*Aurea*'**
This perennial's brightly colored foliage means it can be used in the garden to dramatic effect. The golden, oval leaves are held on stems that grow flat on the ground, forming a dense mat. Yellow, cup-shaped flowers appear in summer.

**H**: 1¼ in (3 cm), **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ● ☼ ◑

**Meconopsis cambrica**
The delightful Welsh poppy is a welcome plant in many gardens; its fresh foliage and flowers make a wonderful show in shaded positions. The flowers, carried on slender stems above the leaves, appear in shades of yellow or orange.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ◑

**Omphalodes cappadocica '*Cherry Ingram*'**
This little perennial is a delight in spring. Its small leaves form a compact clump that starts early into growth. Starry, mauve-blue flowers are carried in small spires and are beautiful for several weeks.

**H**: 8 in (20 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Ophiopogon planiscapus '*Nigrescens*'**
A useful perennial that can be combined with many other plants. It is clump-forming and evergreen with almost black, grasslike foliage. In summer, small, mauve flowers appear, followed by black berries.

**H**: 6 in (15 cm), **S**: 8 in (20 cm)
❄❄❄ ◊ ◑ ☼

**Pachysandra terminalis**
This evergreen, ground-covering plant is one of few that will grow in dry shade under shrubs and trees. Its toothed leaves form a mat of growth that prevents weeds; the plant spreads via underground runners. In summer, white flowers appear.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Primula pulverulenta**
This perennial must have moist, rich soil to thrive. The leaves emerge in spring before the flowerheads. The stout stems, which are covered in a chalky white coating, are striking and contrast well with the rounded heads of small, reddish purple blooms.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄❄ ◑ ● ☼

**Primula vulgaris**
The common primrose is a worthy garden plant and will grow in shady borders under trees and shrubs, in cool rock gardens, or naturalized in grass. In early spring, a succession of yellow, or sometimes white, or even pink, flowers open over many weeks.

**H**: 6 in (15 cm), **S**: 8 in (20 cm)
❄❄❄ ◑ ☼

**Pulmonaria '*Sissinghurst White*'**
With attractive, bell-shaped flowers produced over many weeks in spring, and silver-green foliage, these perennials are excellent garden plants. This dependable selection has white flowers that show up well in shade.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Saxifraga fortunei**
This perennial is remarkable for its late-flowering habit, although some selections bloom during summer. It is a clump-forming plant with handsome, glossy, hand-shaped leaves. Showy flowerheads of white flowers appear before the frost.

**H**: 20 in (50 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Tiarella cordifolia**
A good ground-cover plant, this perennial spreads from runners, colonizing small areas. The hand-shaped leaves are soft and tinted purple. Small, white, pink-tinged flowers are held in short spires during spring.

**H**: 8 in (20 cm), **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Uvularia grandiflora**
A most elegant perennial that bears flowers in mid-spring. Tall, slender stems with oval leaves arise, from which dangle bell-shaped, yellow flowers with long twisted petals. It is not an easy plant and likes cool, moist soil with added organic matter.

**H**: 24 in (60 cm), **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

# Trees, large shrubs, and hedging

**Acer palmatum *'Sango-kaku'***
This elegant Japanese maple is a shade-loving deciduous tree for all seasons. In spring and fall the palmate leaves are distinctly yellow, and in winter the bright lacquer-red stems make a striking feature. Provide shelter and fertile soil.

**H**: 20 ft (6 m); **S**: 15 ft (5 m)
❄❄❄ ◑ ☼

**Amelanchier *x* grandiflora *'Ballerina'***
A small spreading tree for acidic, clay-rich soils and exposed sites. White blossoms smother the bare branches in spring, followed by red, ripening to black, fruits. The oval leaves, bronze-tinted in spring, color red in fall.

**H**: 20 ft (6 m); **S**: 25 ft (8 m)
❄❄❄ ◑ ☼ ☼

**Arbutus unedo**
This evergreen with flaky red-brown bark forms a large shrub or small tree in sheltered gardens. Lily-of-the-valley-like blooms appear in early winter, and the rounded fruits, ripening red in fall, give rise to the common name, strawberry tree.

**H**: 25 ft (8 m); **S**: 25 ft (8 m)
❄❄❄ ◊ ☼

**Betula utilis *var.* jacquemontii**
For winter garden impact, plant this white-barked Himalayan birch as a multistemmed tree or a cluster of three saplings. Cultivars, including 'Jermyns' and 'Grayswood Ghost', have even brighter bark. Long catkins dangle in early spring.

**H**: 60 ft (18 m); **S**: 30 ft (10 m)
❄❄❄ ◊ ◑ ☼ ☼

**Camellia *x* williamsii**
An evergreen, shade-loving shrub that flowers through mid- and late spring and drops its spent flowers neatly. Single to fully double blooms are white through to deep pink, and cultivars are suitable for large pots or as wall shrubs. Requires acidic soil.

**H**: 6–15 ft (2–5 m); **S**: 3–10 ft (1–3 m) ❄❄❄ ◑ ☼

**Cornus controversa *'Variegata'***
Tiered whorls of branches create a distinctive architectural profile, and with bright green and white foliage and flat heads of white flowers in early summer, this charming tree makes a beautiful focal point. Requires neutral to acidic soil.

**H**: 23 ft (7 m); **S**: 23 ft (7 m)
❄❄❄ ◊ ◑ ☼ ☼

**Cornus kousa *var.* chinensis *'China Girl'***
This small conical tree, for neutral to acidic soils, has tiny green flowers in early summer, surrounded by creamy white, petal-like bracts. Fleshy red fruits develop later, followed by purple-red fall leaves.

**H**: 22 ft (7 m); **S**: 15 ft (5 m)
❄❄❄ ◑ ☼ ◑

**Crataegus laevigata *'Paul's Scarlet'***
Like many hawthorns, this hardy tree with a long season of interest is suitable for exposed sites. 'Paul's Scarlet' has a mass of raspberry red blossoms in late spring followed by a crop of red berries loved by birds.

**H**: 25 ft (8 m); **S**: 25 ft (8 m)
❄❄❄ ◊ ◑ ☼ ◑

**Cupressus sempervirens *Stricta Group***
The narrow columns of Italian cypress act like exclamation marks. Informal groups also work well in Mediterranean-style gravel gardens, casting little shade. Maintain a single leading shoot when plants are young.

**H**: 70 ft (20 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ☼

**Fagus sylvatica**
Beech makes an excellent hedge or windbreak, holding on to its coppery fall leaves through winter; the new spring foliage is bright green. Plant bareroot hedging between late fall and early spring. Trim once in late summer.

**H**: 4–20 ft (1.2–6 m); **S**: 4–6 ft (1.2–2 m) ❄❄❄ ◊ ◑ ☼ ◑

**Fatsia japonica**
The false castor-bean plant is a shade-loving evergreen that adds a tropical or contemporary touch with its glossy, hand-shaped leaves and branched flowerheads in fall. Plant in late spring in a sheltered spot. Remove frost-damaged leaves in spring.

**H**: 5–12 ft (1.5–4 m); **S**: 5–12 ft (1.5–4 m)
❄❄ ◑ ◑

**Ilex *x* altaclerensis *'Golden King'***
Sparkling in winter sunshine with its glossy, almost spineless, yellow-edged leaves, this holly makes a neat conical shape with little pruning. Despite its name, 'Golden King' is female and, with male pollen in the vicinity, produces crops of red berries.

**H**: 20 ft (6 m); **S**: 13 ft (4 m)
❄❄❄ ◑ ☼ ◑

# Trees, large shrubs, and hedging

**Magnolia *x* loebneri *'Leonard Messel'***
This rounded tree or large shrub blooms on bare branches in mid-spring. The eye-catching flowers are lilac pink and produced in abundance. Provide fertile, moisture-retentive soil and shelter from wind. Tolerates lime.

**H**: 25 ft (8 m); **S**: 20 ft (6 m)
❄❄❄ ◑ ☼ ◑

**Mahonia x media *'Charity'***
As well as upright flower clusters in late fall and blue-black berries loved by birds, 'Charity' is strikingly architectural, with whorls of large, evergreen, spiny leaves. 'Winter Sun' blooms through winter. Prune lightly after flowering to keep compact.

**H**: 15 ft (5 m); **S**: 12 ft (4 m)
❄❄❄ ◑ ◑

**Malus *x* robusta *'Red Sentinel'***
Crabapples are two-season plants, offering both blossoms and attractive fruits. 'Red Sentinel' is very hardy and bears white flowers in late spring followed by small yellow-red glossy fruits that turn dark red with age and last well into winter.

**H**: 22 ft (7 m); **S**: 22 ft (7 m)
❄❄❄ ◑ ☼

**Photinia *x* fraseri *'Red Robin'***
Although this evergreen can be kept fairly compact through spring and summer pruning, it makes an excellent back-of-border plant or informal hedge. The new growth is bright coppery red and large heads of tiny white flowers appear in late spring.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Phyllostachys nigra**
Black bamboo produces a column of slender arching stems, glossy black when mature and contrasting with the light green leaves. Associate with other architectural plants or grow in a pot. Thin out weak canes from the base and cut off low side shoots.

**H**: 10–15 ft (3–5 m); **S**: 6–10 ft (2–3 m)
❄❄❄ ◑ ☼ ◑

**Prunus *x* subhirtella *'Autumnalis Rosea'***
Perfect for the smaller garden, this cherry bears tiny clusters of delicate, double pale pink flowers during mild periods from fall through to spring. The leaves are narrow, bronze when young, and the habit airy.

**H**: 25 ft (8 m); **S**: 25 ft (8 m)
❄❄❄ ◑ ☼

**Rhamnus alaternus *'Argenteovariegata'***
A white-variegated form of Italian buckthorn with contrasting black stems, this dense evergreen makes a handsome wall shrub. In a sheltered spot it can also be grown freestanding, or clipped into a broad cone or dome.

**H**: 15 ft (5 m); **S**: 12 ft (4 m)
❄❄ ☼

**Sorbus aria *'Lutescens'***
A compact, oval-headed whitebeam, the unfurling felted leaves are silvery-white, becoming light sage with white undersides. In late spring, prominent clusters of white flowers appear, followed by dark red fruits. An ideal lawn specimen. Tolerates chalk.

**H**: 30 ft (10 m); **S**: 25 ft (8 m)
❄❄❄ ☼ ◑

**Sorbus vilmorinii**
This dainty Chinese rowan eventually forms a small tree. The dark, glossy green divided leaves turn rich red-purple in fall, and late spring flowers produce drooping clusters of crimson berries, aging to pink and white. Likes deep, fertile, acidic soil.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◑

**Taxus baccata**
Clipped as a hedge, the shade-loving common yew produces a smooth, dense finish. Cut once in late summer. Plant bare-root plants in the dormant season, ideally before Christmas, and container plants year-round. The whole plant is poisonous.

**H**: 6–12 ft (2–4 m); **S**: 3–5 ft (1–1.5 m)
❄❄❄ ◑ ☼

**Viburnum *x* bodnantense *'Dawn'***
In frost-free periods, from late fall to spring, this upright deciduous shrub produces clusters of pink blooms with a strong scent of sweet almonds. It is happy in clay and requires little pruning. 'Deben' and 'Charles Lamont' are similar cultivars.

**H**: 10 ft (3 m); **S**: 6 ft (2 m)
❄❄❄ ◑ ☼

**Viburnum tinus *'Eve Price'***
This compact and tough evergreen tolerates a wide range of soils and flowers from early winter to mid-spring. Flower clusters are pink in bud, opening white and honey-scented, and these are followed by blue-black berries that are attractive to birds.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◑ ☼

# Climbers

**Clematis *'Bill MacKenzie'***
This vigorous cultivar flowers from midsummer to late fall and bears intriguing "lemon peel" blooms with dark red centers. Fluffy silver seed-heads follow, and the foliage is light green and feathery. Prune stems almost to the ground in early spring.

**H**: 22 ft (7 m)
❄❄❄ ◑ ☼ ◑

**Clematis *'Etoile Violette'***
From midsummer through to fall, violet-purple nodding blooms are produced on the new season's growth. As with all viticella clematis, prune hard in early spring to about 12 in (30 cm) from ground level, just above a pair of fat buds.

**H**: 15 ft (5 m)
❄❄❄ ◑ ☼ ◑

**Clematis *'Markham's Pink'***
This dainty, double-flowered clematis has rose-pink blooms from spring to early summer and silvery ornamental seedheads. It is ideal for decorating a trellis, covering a low wall, or training up a shrub or small tree. Prune only to remove dead stems.

**H**: 8 ft (2.5 m)
❄❄❄ ◑ ☼ ◑

**Clematis *'Perle d'Azur'***
Profuse in bloom, this sky-blue, small-flowered clematis shines from midsummer to fall even on a north-facing wall. Prune back to about 12 in (30 cm) from ground level in spring, just above strong buds. 'Prince Charles' is more compact.

**H**: 15 ft (5 m)
❄❄❄ ◑ ☼ ●

**Euonymus fortunei *'Silver Queen'***
Though usually grown as ground cover, euonymus cultivars will climb walls and fences, self-clinging via aerial roots. 'Silver Queen' makes dense, bushy wall cover, adding light to a shady view, and the white edges turn pink in winter. Trim to neaten.

**H**: 20 ft (6 m)
❄❄❄ ◊ ◑ ☼ ●

**Hedera helix *'Glacier'***
The gray-green, three- to five-lobed leaves of this English ivy are marbled with a variable white margin that is brightest in good light. Self-clinging stems make a close-knit wall or fence covering, and it can be pruned at any time to control spread.

**H**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Hydrangea anomala *subsp.* petiolaris**
Although this deciduous, self-clinging climber takes a few years to begin climbing and flowering in earnest, it is a stunning sight on a shady wall when covered in its white midsummer blooms. It has yellow fall foliage.

**H**: 50 ft (15 m)
❄❄❄ ◑ ☼ ☀

**Parthenocissus henryana**
This well-behaved form of Virginia creeper develops silvery veins and red tints in partial shade but has better fall color in full sun, when the leaves turn crimson before falling. It clings to vertical surfaces via sticky-ended tendrils. Prune to control size.

**H**: 30 ft (10 m)
❄❄❄ ◑ ☼ ☀

**Pileostegia viburnoides**
An evergreen, self-clinging climber that thrives in sheltered sites on fertile soil. The architectural leaves are long, leathery and pointed and, in late summer and fall, frothy sprays of white flowers appear. May take a few years to reach flowering size.

**H**: 20 ft (6 m)
❄❄ ◊ ☼ ☀

**Schizophragma integrifolium**
This self-clinging, deciduous hydrangea relative blooms in midsummer and bears heads of tiny fertile flowers surrounded by showy sterile bracts. *Schizophragma hydrangeoides* 'Roseum' has pink bracts. Shade the roots and provide initial support.

**H**: 40 ft (12 m)
❄❄ ◑ ☼ ◐

**Trachelospermum jasminoides**
Confederate or star jasmine is an evergreen twining climber with small, fragrant, white pinwheel blooms in midsummer. Thrives in a hot, sheltered site. Provide wire supports. Growth may be slow at first. *Trachelospermum asiaticum* is similar.

**H**: 28 ft (9 m)
❄❄ ◊ ☼

**Vitus vinifera *'Purpurea'***
The leaves of this deciduous vine are intricately cut and a rich red-purple shade, becoming darker in fall when clusters of unpalatable small, round, purple grapes ripen. Provide support for the tendrils to cling to and plant on fertile soil.

**H**: 22 ft (7 m)
❄❄❄ ◊ ◑ ☼

# Medium-sized shrubs

**Acer palmatum *var.* dissectum *Dissectum Atropurpureum Group***
Purple-red, finely cut foliage, which turns a vibrant red in fall, covers the arching stems of this slow-growing deciduous shrub. Like other Japanese maples, it prefers rich, moisture-retentive soil and a sheltered site.

**H**: 6 ft (2 m); **S**: 10 ft (3 m)
❄❄❄ ◑ ☼ ◑

**Aucuba japonica *'Variegata'***
Spotted laurel is a shade-loving evergreen whose gold-splashed leaves lighten gloomy corners. Tolerant of pollution, it is ideal for city gardens. Female forms, like 'Crotonifolia' and 'Variegata', have bright red berries. Remove frost-damaged tips in spring.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ◑

**Buddleja *'Lochinch'***
This butterfly bush has silvery-white stems and gray-green leaves that make a lovely foil for the pale lavender flowerheads, which appear from mid- to late summer. Each tiny bloom has an orange "eye." Prune back hard in early spring.

**H**: 8 ft (2.5 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ☼

**Ceanothus *x* delileanus *'Gloire de Versailles'***
A deciduous California lilac, this bushy shrub flowers prolifically from midsummer to mid-fall. The blooms are a soft powder-blue and work well in a mixed border. Prune to a low framework in mid-spring.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

**Choisya *'Aztec Pearl'***
This rounded, evergreen Mexican orange blossom has glossy narrow leaves that produce an airy effect. Flowering abundantly in late spring, with a second late-summer show, its star-shaped blooms are pink-tinged white and fragrant.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Choisya ternata *Sundance***
Lime-colored and slow-growing, this popular, neat evergreen makes a vibrant addition to a shady border; it rarely flowers. On drier soils or in full sun, the foliage is golden. Avoid poor soils, and frost-prone or exposed sites. A good container plant.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ☀

**Cornus alba *'Sibirica'***
This slowly suckering dogwood has red fall foliage and lacquer-red winter stems. Plant in groups for maximum impact, and prune hard in early spring to promote plenty of new growth with vibrant color. Tolerates waterlogged clay.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◑ ● ☼ ◑

**Cornus alba *'Spaethii'***
Variegated dogwoods provide foliage contrast in mixed borders and help to lighten evergreen plantings. When established, prune out one-third of the oldest growth in early spring to promote the cherry-red winter stems. Remove all-green shoots.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◑ ● ☼ ◑

**Daphne bholua *'Jacqueline Postill'***
This late-winter-flowering evergreen daphne is hard to beat for fragrance, especially when planted in a spot sheltered from wind. The small but numerous blooms are deep purple-pink outside and white within. Mulch to retain moisture.

**H**: 6–12 ft (2–4 m); **S**: 5 ft (1.5 m)
❄❄❄ ◑ ☼ ◑

**Escallonia laevis *'Gold Brian'***
This compact cultivar is grown mainly for its attractive bright, lime-green to gold, glossy foliage. A reliable evergreen for most gardens, it resents exposure to cold, drying winds. Deep pink blooms are produced during summer. Pruning is rarely required.

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄❄ ◊ ◑ ☼ ◑

**Fargesia murielae *'Simba'***
An excellent dwarf form of bamboo, 'Simba' is well behaved either in the border or in a large container. The fluttering leaves clothing the upright stems are a fresh, light green. Thin out weak stems, and some older than three years, to maintain an airy habit.

**H**: 6 ft (2 m); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ◑

**Hebe *'Great Orme'***
A long-flowering hebe with tapering, rich pink, fading to white blooms from midsummer to fall. The stems are purple, contrasting attractively with the narrow, glossy, mid-green leaves. Ideal for city or seaside gardens with shelter from cold winds.

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄ ◊ ☼

# Medium-sized shrubs

**Hebe salicifolia**
A hardy species, this narrow-leaved hebe flowers between early summer and mid-fall. Tapering white or lilac-tinged blooms are borne on upright to arching stems clothed in light green leaves. *Hebe* 'Spender's Seedling' is similar but more compact.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ☼

**Hydrangea arborescens *'Annabelle'***
The blooms of this long-flowering American hydrangea first appear in early summer; they are fresh apple-green in bud, expanding to form very large creamy-white domes. They then make attractive papery heads in fall. Prune lightly in spring.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◑ ☼ ◑

**Hydrangea paniculata**
With abundant cone-shaped creamy-white heads in late summer, forms of *H. paniculata* are ideal for the mixed border; pink tints often develop in fall, especially in cultivars like 'Unique'. Prune to a low framework each spring for larger blooms.

**H**: 10 ft (3 m); **S**: 8 ft (2.5 m)
❄❄❄ ◑ ☼ ◑

**Hydrangea *'Preziosa'***
This compact hydrangea has dark mahogany stems and red fall tints. Late-summer flowers beautifully combine young, pale pink blooms with mature heads of deep red, tinted purple in acidic soil. Trim shoot tips to the first fat buds in spring.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m)
❄❄ ◑ ☼ ◑

**Hydrangea serrata *'Bluebird'***
A lacecap type with narrow, tapered leaves, this dainty hydrangea bears porcelain-blue heads over a long period through summer into fall. 'Grayswood', with mauve blooms, acquiring raspberry tints in fall, is slightly taller at 6 ft (2 m).

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄ ◑ ☼ ◑

**Juniperus *x* pfitzeriana *'Sulphur Spray'***
The arching to upright branches of this juniper are covered in feathery sprays of pale sulfur-tinted foliage, the coloring most pronounced at the shoot tips. Stems may be removed to control height and spread.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m)
❄❄❄ ☼ ◑ ☼

**Nandina domestica**
Heavenly bamboo is an evergreen or semievergreen shrub with upright stems. The divided leaves are tinted coppery red when young and develop strong red-purple tones in winter. Midsummer flower sprays are white, developing into orange-red berries.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)
❄❄ ◑ ☼

**Olearia *x* haastii**
This small-leaved evergreen is neat and compact and thrives in sheltered urban gardens or in seaside areas. The leathery leaves have a white felted reverse. Frothy heads of tiny white, yellow-centered daisies appear between mid- and late summer.

**H**: 6 ft (2 m); **S**: 10 ft (3 m)
❄❄ ◊ ☼

**Osmanthus *x* burkwoodii**
In mid-spring this small-leaved evergreen is smothered in clusters of tiny white tubular blooms with a strong perfume. A compact shrub, it doesn't require pruning but can be clipped immediately after flowering to form simple topiary shapes.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼ ◑

**Phormium *'Alison Blackman'***
A New Zealand flax with olive-green-centered leaves carrying gold stripes with a narrow red margin. Tall flower shoots sometimes appear in summer. Tougher than many other colored-leaf cultivars. 'Sundowner' has similar coloring but is larger.

**H**: 4½ ft (1.4 m); **S**: 4½ ft (1.4 m)
❄❄ ◊ ◑ ☼

**Phormium tenax *Purpureum Group***
Ideal for a dramatic focal point in the border, members of this group have tapering, strap-shaped leaves that arch at the tip and, when mature, produce towering, rodlike flower stems. The cultivars 'Platt's Black' and 'All Black' are particularly dark.

**H**: 6 ft (2 m); **S**: 8 ft (2.5 m)
❄❄ ◊ ◑ ☼

**Physocarpus opulifolius *'Diabolo'***
Use this dark-purple-leaved form of the deciduous ninebark for foliage contrast in the mixed border. The leaves are trilobed and toothed, and in early summer dome-shaped heads of pale pink blooms appear. Spring-prune for larger leaves.

**H**: 6–8 ft (2–2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

# Medium-sized shrubs

**Pittosporum *'Garnettii'***
These New Zealand natives make useful evergreen backdrops or wall shrubs for sheltered town gardens and seaside plots. 'Garnettii' has mahogany stems with gray-green, white-edged leaves, pink-tinged in winter, and dark purple, scented spring blooms.

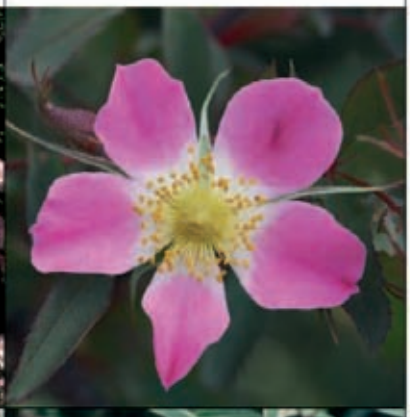
**H**: 10 ft (3 m); **S**: 6 ft (2 m)
❄❄ ☼

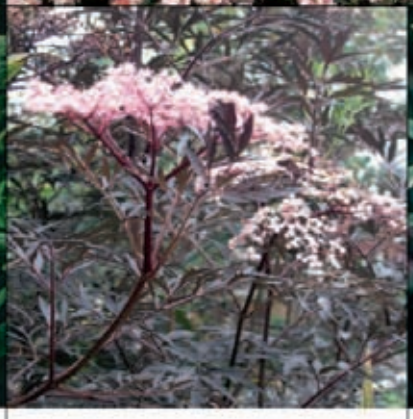
**Rhododendron yakushimanum**
An evergreen for acidic soil that makes a neat dome shape. It produces rose-pink buds in spring that open to large heads of white and pale pink bell-shaped blooms. The new leaf growth, covered in a colorful felting of light cinnamon, is also a feature.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ☼

**Rosa glauca**
Even when not in flower, this shrub rose makes an attractive foil for flowers in the mixed border. Arching red-purple stems bear soft purple-gray leaves and, in summer, single cerise-tinted blooms appear, later producing dark red spherical hips.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)
❄❄❄ ◑ ☼ ☼





**Rosa rugosa *'Alba'***
A shrub rose with apple-green, virtually disease-free foliage and yellow fall color. All summer, flushes of large, single, fragrant white blooms appear, each with a yellow eye. Showy tomato-red hips follow, which are attractive to finches.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ☼

**Sambucus nigra *'Black Lace'* (syn. *'Eva'*)**
Aptly named, this deciduous elderberry has finely-cut, purple-black foliage and, if only lightly pruned, flat plates of pink summer blossoms and black berries. Prune to a low framework in early spring to keep compact.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◑ ☼ ☼

**Sarcococca hookeriana *var.* digyna**
The upright stems of this suckering evergreen shrub are clothed in shiny, narrow, tapering leaves. In winter, tiny blooms with tufts of cream anthers release a pervasive perfume, giving rise to the common name of sweet box. Shiny black berries follow.

**H**: 5 ft (1.5 m); **S**: 6 ft (2 m)
❄❄❄ ◑ ☼ ☼

**Skimmia japonica *'Rubella'***
This glossy, evergreen woodlander has showy cones of crimson flower buds that develop in fall and open to sweetly fragrant white blooms in spring. This cultivar is male, so it does not produce berries. It is slow-growing, and needs shelter and fertile soil.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m)

**Syringa meyeri *'Palabin'***
This dwarf lilac has fragrant, lavender-pink blooms in late spring and early summer and small oval leaves. It thrives in neutral to alkaline soil. *Syringa pubescens* subsp. *microphylla* 'Superba' flowers intermittently from spring to fall.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)

**Taxus baccata *'Standishii'***
Ideal for lightening a shady area or as a focal point among ground cover, this golden-leaved yew makes a compact column over time. Prune back competing leading shoots to reduce spread. *Taxus baccata* 'Fastigiata Aureomarginata' is larger.

**H**: 5 ft (1.5 m); **S**: 24 in (60 cm)

**Viburnum *x* burkwoodii *'Anne Russell'***
In mid- and late spring this compact, deciduous viburnum produces domed heads of waxy-textured, sweetly fragrant blooms that are pink in bud, opening white. Red fruits and colorful tints feature in fall.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)

**Viburnum davidii**
This evergreen has handsome dark leaves, held on red leaf stalks, with distinctive, deeply grooved, parallel veins giving a pleated effect. Small flower clusters in late spring produce lustrous blue berries on female shrubs when both sexes are present.

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)

**Weigela florida *'Foliis Purpureis'***
The bronzy-purple foliage of this compact, deciduous weigela is its main feature. In late spring and early summer, clusters of crimson buds open to funnel-shaped blooms with pale pink interiors, and these contrast well with the dark leaves.

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)

# Low shrubs, shorter perennials, and ground-cover plants

**Acorus gramineus *'Ogon'***
This variegated Japanese rush produces fans of grassy foliage with bold gold and green stripes. Often grown as a marginal plant in ponds, this variety also thrives in fertile, moisture-retentive soil and makes an excellent foliage container plant.

**H**: 10 in (25 cm); **S**: 6 in (15 cm)
❄❄❄ ◑ ● ☼ ☀

**Anaphalis triplinervis *'Sommerschnee'***
Pearly everlasting is a clump-forming perennial with felted, gray-green, lance-shaped leaves. From mid-to late summer it bears ball-shaped flowers made of pure white papery bracts. Avoid very dry soil in summer.

**H**: 28 in (70 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼ ☀

**Armeria maritima**
Varieties of sea pink or thrift are drought-tolerant evergreens that make fine grassy tussocks. The abundant white, pink, or red-purple flowers of *A. maritima* are borne in spherical clusters between late spring and early summer.

**H**: 8 in (20 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ☼

**Artemisia schmidtiana *'Nana'***
Both the species and the dwarf form 'Nana' create low domes of bright, silvery-green, filigree foliage. Close-planted to form an evergreen carpet, they are ideal as drought-tolerant ground cover or to front a dry border. The flowers are insignificant.

**H**: 3 in (8 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ☼

**Artemisia stelleriana *'Boughton Silver'***
The white-felted foliage of this low evergreen is intricately cut and looks more like lace than leaves. Use it to fill gaps between other plants, especially toward the front of the border, or to provide textural contrast in a container.

**H**: 6 in (15 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ☼

**Arum italicum *'Marmoratum'***
From late fall through to mid-spring, the marbled, arrow-shaped leaves of lords and ladies cover the ground. In spring, pale green flowers appear, followed by gleaming spikes of fall berries. Good on heavier soils, it needs moisture in sunshine.

**H**: 12 in (30 cm); **S**: 6 in (15 cm)
❄❄❄ ◑ ☼ ☀

**Astilbe *'Bronce Elegans'***
This pretty, dwarf astilbe has finely cut, rich copper foliage in spring and feathery pink plumes from mid- to late summer. Plants form creeping herbaceous colonies and are suitable for the front of a border. Tolerates full sun given plentiful moisture.

**H**: 12 in (30 cm); **S**: 10 in (25 cm)
❄❄❄ ◑ ● ☼ ☀

**Bergenia cordifolia *'Purpurea'***
This evergreen elephant's-ears has magenta bell-shaped flowers in late winter and rich purple-red leaf tones through fall and winter. Its large, glossy, rounded leaves make a strong contrast with grassy foliage plants. *Bergenia purpurascens* is similar.

**H**: 24 in (60 cm); **S**: 30 in (75 cm)
❄❄❄ ◑ ☼ ☀

**Carex flagellifera**
One of the New Zealand sedges, this evergreen has upright then arching clumps of fine wiry foliage, tinted gingery-brown. Plant singly to accent low creepers, or in multiples for ground cover with a contemporary look. *Carex testacea* is similar.

**H**: 3½ ft (1.1 m); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ☀

**Carex oshimensis *'Evergold'***
This bright, gold and green-striped evergreen sedge from Japan makes hummocks of narrow, arching, grassy leaves. Planted in groups, it provides colorful ground cover, but it also works well in containers. Remove or trim brown leaves in spring.

**H**: 12 in (30 cm); **S**: 14 in (35 cm)
❄❄❄ ◑ ☼ ●

**Ceratostigma plumbaginoides**
This creeping plant attracts the eye in late summer when the red stems are studded with gentian-blue blooms. In fall, the carpet of bright green leaves turn red or purple, providing a striking foil for the remaining flowers. Avoid very poor dry soils.

**H**: 18 in (45 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼

**Cistus *x* dansereaui *'Decumbens'***
From late spring to midsummer, this rock rose produces a succession of pure white, tissue-paper blooms marked with maroon blotches. The sticky evergreen foliage makes fine ground cover for banks and hot, dry borders. *Cistus* x *hybridus* is similar.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄ ◊ ☼

# Low shrubs, shorter perennials, and ground-cover plants

**Cistus *x* lenis *'Grayswood Pink'***
Blooming in summer, this pretty pink-flowered rock rose is one of the hardiest in cultivation. Low-growing, it spreads to cover a large area, sometimes rooting where the stems touch the ground. Useful for gravel gardens, walls, and banks.

**H**: 12 in (30 cm); **S**: 10 ft (3 m)
❄❄❄ ☼

**Convolvulus cneorum**
With leaves like strips of silvery metal, this compact, dome-shaped evergreen gleams in sunshine. Starting in spring, flushes of pink buds open to white funnel-shaped blooms. Thrives in shelter in poor, slightly alkaline soil with sharp winter drainage.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄ ☼

**Cotoneaster horizontalis**
This tough, deciduous shrub produces a herringbone pattern of branches clothed in small, glossy, dark green leaves that turn red in fall. In late spring, it is smothered in tiny blossoms that ripen to long-lasting red berries. It makes good ground or wall cover.

**H**: 4 ft (1.2 m); **S**: 5 ft (1.5 m)
❄❄❄ ◑ ☼

**Cyclamen hederifolium**
Carpets of this self-seeding cyclamen steadily build up under established trees and shrubs, thriving in soil rich in leafmold. The delicate pink blooms appear in fall before the marbled, arrow-shaped leaves, which last throughout winter and spring.

**H**: 5 in (13 cm); **S**: 6 in (15 cm)
❄❄❄ ◑

**Diascia barberae *'Blackthorn Apricot'***
Providing summer-flowering ground cover in well-drained gardens, several diascias are hardy, especially the brick-pink 'Ruby Field', but need plentiful summer moisture. Clip over in spring. They overwinter best in containers.

**H**: 10 in (25 cm); **S**: 20 in (50 cm)
❄❄ ◑ ☼

**Dicentra *'Stuart Boothman'***
This low-growing bleeding heart has feathery blue-gray foliage and, from mid-spring to late summer, arching sprays of deep pink blooms. It prefers fertile, moisture-retentive soil, conditions that prolong both flowering and foliage displays.

**H**: 12 in (30 cm); **S**: 16 in (40 cm)
❄❄❄ ◑

**Erica carnea *'Springwood White'***
Between midwinter and mid-spring, the carpet of emerald-green foliage is covered in tiny, white, honey-scented flowers that attract early bees. It has a trailing habit. Another excellent white is *Erica* x *darleyensis* 'Silberschmelze'. Clip after flowering.

**H**: 6 in (15 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ◑ ☼

**Erigeron karvinskianus**
This dainty fleabane self-seeds freely, growing in cracks in walls and paving and forming colonies in gravel. All summer, a profusion of little daisylike blooms are produced; these mature from white through to deep pinky-purple, creating a two-tone effect.

**H**: 6 in (15 cm); **S**: 3 ft (1 m)
❄❄❄ ◊ ☼

**Euonymus fortunei *'Emerald 'n' Gold'***
With copious gold variegation, this evergreen shrub is ideal for a winter border. As temperatures plummet, the foliage becomes pink-tinged. May be clipped to simple shapes. 'Canadale Gold' is similar but stronger growing.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ◑

**Geranium *'Ann Folkard'***
From midsummer to mid-fall, this cranesbill's trailing stems produce vivid magenta-purple blooms, each with a prominent black eye. The deeply cut, five-lobed leaves are a bright lime green. Foliage darkens with age and in excessive shade.

**H**: 24 in (60 cm); **S**: 3 ft (1 m)
❄❄❄ ◑ ☼ ◑

**Geranium *'Johnson's Blue'***
A firm favorite with gardeners, this light-lavender-blue-flowered cranesbill is easy to please and blooms from late spring well into summer. The dish-shaped flowers are enhanced by prominent pinky-blue centers. *G.* 'Rozanne' is longer in bloom.

**H**: 18 in (45 cm); **S**: 30 in (75 cm)
❄❄❄ ◑ ☼ ◑

**Geranium sanguineum**
The bloody cranesbill forms neat hummocks of finely cut leaves and bears small magenta-pink flowers for many weeks in summer. Ideal for gravel gardens and raised beds, it also provides good fall color. 'Album' is white-flowered.

**H**: 8 in (20 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼ ◑

# Low shrubs, shorter perennials, and ground-cover plants

**Hakonechloa macra *'Aureola'***
The arching, ribbonlike leaves of this Japanese grass are striped yellow and lime green, developing red tints in full sun, and becoming greener in deep shade. Best in slightly acidic soil and excellent in containers. Cut back foliage in spring.

**H**: 14 in (35 cm); **S**: 16 in (40 cm)
❄❄❄ ◑ ☼ ☀

**Hebe cupressoides *'Boughton Dome'***
A remarkably hardy, neat evergreen with gray-green foliage in the form of overlapping scales. The domed shape contrasts well with narrow-leaved ground cover; or plant it in groups to create a repeating pattern.

**H**: 12 in (30 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ☼

**Hebe *'Red Edge'***
The gray-green leaves of this small-leaved, hardy hebe are edged with a fine red line and become red-tinged in winter. Small, lilac-blue flowers appear in summer, unless plants have been clipped over in late spring to enhance the domed form.

**H**: 18 in (45 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ☼

**Hedera helix *'Parsley Crested'***
Non-variegated ivies are useful for covering the dry ground beneath trees, or for making a lawn substitute surrounded by paving. 'Parsley Crested' has mid-green leaves with an undulating margin. 'Manda's Crested' is similar but copper-tinted in winter.

**H**: 8 in (20 cm); **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ☀

**Hedera helix *'Little Diamond'***
An aptly named ivy, perfect for the front of a border or edging a container. The small, diamond-shaped leaves are marbled gray-green with a creamy-white edge. A compact, slow-growing plant, it provides dense, bushy cover.

**H**: 3 in (8 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼ ☀

**Helleborus *x* hybridus**
This group of mostly evergreen perennials flowers from midwinter to mid-spring in colors from white, through pinks and reds, to dark maroon. Centers are usually speckled. Remove withered foliage. Prefers heavy, fertile, moisture-retentive soil.

**H**: 18 in (45 cm); **S**: 18 in (45 cm)
❄❄❄ ◑ ◑ ☀

**Heuchera *'Plum Pudding'***
A compact evergreen perennial with heart-shaped, lobed leaves colored red-purple with deeper veining. From late spring, dark wiry stems carry tiny white flowers. 'Pewter Moon' has purple leaves overlaid with silver. Susceptible to vine weevil.

**H**: 16 in (40 cm); **S**: 12 in (30 cm)
❄❄❄ ◑ ☼ ◑

**Hosta *'Halcyon'***
An elegant hosta with tapered, slug-resistant, gray-blue leaves and soft lavender summer flowers. The blue hostas 'Krossa Regal' and 'Big Daddy', and the yellow-centered 'Great Expectations', are also slug-resistant. For added protection, grow in pots.

**H**: 16 in (40 cm); **S**: 28 in (70 cm)
❄❄❄ ◑ ● ◑ ●

**Juniperus squamata *'Blue Carpet'***
This blue-leaved conifer makes a dense evergreen, weed-suppressing carpet and ultimately needs room to spread. It tolerates thin, chalky soil and requires minimal care, but may be pruned to control its spread by cutting out whole branches.

**H**: 12 in (30 cm); **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼

**Lavandula angustifolia *'Hidcote'***
One of the best dwarf lavenders, 'Hidcote' makes mounds of silvery gray leaves topped in midsummer by dark purple spikes. To keep plants bushy and well clothed in foliage, clip over with shears after flowering. 'Munstead' is similar but paler.

**H**: 24 in (60 cm); **S**: 30 in (75 cm)
❄❄❄ ◊ ☼

**Leucothoe *Scarletta* (syn. *'Zeblid'*)**
This member of the heather family has small, glossy, evergreen leaves that turn a rich bronze red in fall, and it produces equally colorful new foliage. It requires fertile, acidic, moisture-retentive soil and shelter from wind. A good container plant.

**H**: 24 in (60 cm); **S**: 3½ ft (1.1 m)
❄❄❄ ◑ ☼

**Libertia peregrinans**
A slow-spreading grassy evergreen from New Zealand with amber-tinged foliage that brightens in winter, and white, starry spring blooms. The warm-brown-leaved 'Taupo Sunset' is an eye-catching newcomer with contrasting white flowers.

**H**: 20 in (50 cm); **S**: 20 in (50 cm)
❄❄ ◊ ◑ ☼ ◑

# Low shrubs, shorter perennials, and ground-cover plants

**Liriope muscari**
Lilyturf is a hard-working evergreen perennial that makes a slow-spreading tuft of narrow, leathery, strap-shaped leaves. In late summer, long-lasting spikes of violet-purple flowers emerge. Good as fall-interest path edging or shady ground cover.

**H**: 12 in (30 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ◑ ☼ ☀

**Muscari armeniacum**
Grape hyacinth flowers in mid-spring, attracting early bees with its honey-scented blooms. The dense spikes of blue flowers emerge through grassy carpets. Unusually, this bulb's leaves appear in late summer and last until late spring. 'Blue Spike' is a double.

**H**: 8 in (20 cm); **S**: 2 in (5 cm)

**Narcissus *'February Gold'***
Dwarf, cyclamineus daffodils are invaluable for creating early spring color, and most naturalize well in informal lawns and under trees. With the narrow foliage dying down gracefully, they are also suitable for borders, even in heavy soil.

**H**: 12 in (30 cm); **S**: 3 in (8 cm)
❄❄❄ ◑ ☼ ☀

**Ophiopogon planiscapus *'Nigrescens'***
Black mondo grass, actually a member of the lily family, makes a spreading carpet of virtually black, strappy leaves. Tolerating a wide range of conditions, it keeps its color well even in dry shade.

**H**: 8 in (20 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ◑ ☼ ☀

**Origanum laevigatum *'Herrenhausen'***
This pretty ornamental oregano is a drought-buster. With purple-tinged leaves and stems, it makes excellent edging. From midsummer, it produces small, rounded heads of pink blooms followed by pretty seedheads.

**H**: 18 in (45 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ☼

**Osteospermum jucundum**
This South African daisy bears long-stemmed flowers, with a darker "eye" and smoky reverse, through summer and into fall. The evergreen carpeting foliage can be used to flow over the edge of retaining walls or to soften paving on a hot, sunny patio.

**H**: 20 in (50 cm); **S**: 36 in (90 cm)
❄❄❄ ◊ ☼

**Pachysandra terminalis *'Variegata'***
The cream-variegated form of this glossy-leaved, evergreen ground cover is slightly slower-growing than the species and useful for lightening areas in dappled shade beneath trees or shrubs. Best given shelter and acidic, moisture-retentive soil.

**H**: 10 in (25 cm); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ☀

**Penstemon *'Evelyn'***
Unlike most border penstemons, this evergreen, narrow-leaved perennial is compact and ideal for edging a bed or for planting in pots. The rose-pink tubular blooms continue from midsummer into fall, especially with frequent deadheading.

**H**: 24 in (60 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ☼

**Persicaria affinis *'Superba'***
This creeping knotweed produces mini pokers of crimson-opening-to-pink blooms from midsummer to fall. The neat carpet of foliage turns brown in winter but remains attractive. Good between rocks and for fronting shrub borders.

**H**: 10 in (25 cm); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ☼

**Phormium *'Bronze Baby'***
A dwarf New Zealand flax, this cultivar has deep purple, arching, strap-shaped leaves that form bold tufts among low-growing plants. It is also excellent for providing height in containers. Protect from sharp frost with a thick mulch of bark.

**H**: 32 in (80 cm); **S**: 32 in (80 cm)
❄❄ ◊ ◑ ☼

**Pieris japonica *'Purity'***
Many varieties of *Pieris japonica* are compact and ideal for urban gardens. 'Purity' produces upright sprays of white, lily-of-the-valley flowers in spring and pale green new leaves in whorls at the shoot tips. Provide acidic soil and avoid frosty sites.

**H**: 36 in (90 cm); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ☼

**Pinus mugo *'Mops'***
This slow-growing, dwarf mountain pine is almost spherical in habit, with multiple upright stems that are covered in long, evergreen, needle-like leaves. Perfect for gravel-mulched gardens with rocks and pebbles, or as specimens in containers on the patio.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄❄ ◊ ☼

# Low shrubs, shorter perennials, and ground-cover plants

**Polystichum setiferum** ***Divisilobum Group***
This evergreen soft shield fern has highly dissected, dark green fronds with a felted texture. It makes an attractive sculptural feature in winter shade borders and containers. Remove tired fronds in spring.

**H**: 28 in (70 cm); **S**: 28 in (70 cm)
❄❄❄ ◑ ☼ ☀

**Potentilla fruticosa** ***'Primrose Beauty'***
Shrubby cinquefoil does well in clay, and soft-colored cultivars also enjoy partial shade. This compact, gray-green-leaved form flowers from summer to fall. Prune in spring, removing a third of the oldest stems.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ◑

**Rhodanthemum hosmariense**
Almost never out of flower, this silver-green, filigree-leaved evergreen produces most of its daisylike blooms from early to late summer. Use it to soften the edge of a sunny retaining wall, or in gaps in paving, and in poor, stony soil.

**H**: 12 in (30 cm); **S**: 12 in (30 cm)
❄❄❄ ◊ ☼

**Rhododendron** ***'Vuyk's Scarlet'***
This dwarf evergreen has a low profile, making it ideal for the front of a shrub border in acidic soil. The scarlet-tinged crimson blooms are single bells with wavy margins and are produced in abundance during mid- or late spring. Tolerates sun.

**H**: 30 in (75 cm); **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼ ◑

**Rosa** ***Surrey***
One of the best of the County series, this ground-cover rose bears double pink, lightly fragrant blooms in flushes between midsummer and fall. Relatively disease-free. Cut plants back in spring with a hedge trimmer. Also try the Flower Carpet series.

**H**: 32 in (80 cm); **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼

**Scabiosa** ***'Butterfly Blue'***
'Butterfly Blue', and the lilac-pink 'Pink Mist', are dainty mini scabious, flowering over a long period through summer into fall, especially if deadheaded regularly. Plant at the border edge or in containers. The flowers attract bees and butterflies.

**H**: 16 in (40 cm); **S**: 16 in (40 cm)
❄❄❄ ◊ ☼

**Sedum *'Ruby Glow'***
Carpeting stonecrops, like 'Ruby Glow' and 'Vera Jameson', combine dusky purple-tinged succulent leaves with crimson flowerheads that appear from midsummer to fall. Effective *en masse* in gravel gardens. Drought-resistant and attractive to butterflies.

**H**: 10 in (25 cm); **S**: 18 in (45 cm)
❄❄❄ ☼ ◑

**Sempervivum tectorum**
Common houseleek, also named hen-and-chicks as the rosettes of leaves are surrounded by offshoots, bears upright, red-purple flower stems in summer; the leaves may also be red-tinted. These evergreen succulents are used for living roofs.

**H**: 6 in (15 cm); **S**: 20 in (50 cm)
❄❄❄ ☼

**Sisyrinchium striatum *'Aunt May'***
This cultivar produces white-striped evergreen leaf fans from which upright stems of creamy flowers arise in summer. Architectural in character, they work well planted in swaths in gravel gardens. Deadhead to prevent seeding.

**H**: 20 in (50 cm); **S**: 10 in (25 cm)
❄❄❄ ☼

**Stipa tenuissima**
Although this diaphanous grass makes a good pot specimen, it works best weaving through borders or planted in clumps near paving. It bears pale, biscuit-colored flower stems through summer, and the light green leaves fade but remain attractive all winter.

**H**: 24 in (60 cm); **S**: 12 in (30 cm)
❄❄❄ ☼

**Yucca filamentosa *'Bright Edge'***
This brightly variegated form of Adam's needle is best planted as a single specimen or in small groups mulched with gravel or pebbles. Spires of creamy bells may appear in summer, but this is chiefly an evergreen foliage plant. Makes a fine container specimen.

**H**: 30 in (75 cm); **S**: 4 ft (1.4 m)
❄❄❄ ☼

**Yucca flaccida *'Ivory'***
These architectural evergreens can be temperamental about blooming, but 'Ivory' produces its exotic-looking flowers freely. In summer, tall stems bearing a profusion of green-tinted cream bells rise from the basal rosette of blue-green, swordlike leaves.

**H**: 22 in (55 cm); **S**: 5 ft (1.5 m)
❄❄❄ ☼

# Perennials and ornamental grasses

**Acanthus spinosus**
This statuesque perennial sends up glossy leaves in early spring that expand to form a mound of deeply toothed blades armed with spines. In early summer, spires of white-hooded blooms with long-lasting purple bracts appear. A paving or gravel specimen.

**H**: 4½ ft (1.4 m); **S**: 36 in (90 cm)
❄❄❄ ◊ ◑ ☼ ☼

**Agapanthus *'Loch Hope'***
This Nile lily has clumps of strap-shaped leaves and tall stems topped with striking round heads of deep blue flowers. Combining well with hot-colored blooms, they brighten flagging displays in late summer and early fall. Mulch in winter.

**H**: 4 ft (1.2 m); **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Allium hollandicum *'Purple Sensation'***
In early summer, this ornamental onion bears drumstick heads of rich purple above a tuft of gray-green leaves. The sculptural seedheads are long-lasting and good for drying, but seedlings will produce paler blooms.

**H**: 3 ft (1 m); **S**: 3 in (7 cm)
❄❄❄ ◊ ☼ ☼

**Anemanthele lessoniana**
The pheasant's-tail grass, formerly *Stipa arundinacea*, makes a dense clump of narrow, ribbonlike foliage. Arching purple-tinted flower stems reach almost to the ground and, from fall through winter, the olive leaves are tinted orange and red.

**H**: 36 in (90 cm); **S**: 4 ft (1.2 m)
❄❄❄ ◊ ◑ ☼ ☼

**Anemone hupehensis *'Hadspen Abundance'***
An upright, free-flowering perennial that bears unevenly shaped, deep pink blooms with golden stamens from mid- to late summer. The vine-like leaves form substantial clumps. Also try *Anemone* x *hybrida* cultivars.

**H**: 36 in (90 cm); **S**: 16 in (40 cm)
❄❄❄ ◑ ☼ ☼

**Aster *x* frikartii *'Mönch'***
Superior to most Michaelmas daisies, this adaptable lavender-blue aster blooms from midsummer to fall. It doesn't usually need staking and has good mildew resistance. Working well with most color schemes, it is also charming with ornamental grasses.

**H**: 28 in (70 cm); **S**: 16 in (40 cm)
❄❄❄ ◑ ☼ ☼

**Astrantia *'Hadspen Blood'***
This easy-care perennial colonizes wilder parts of the garden in dappled shade but is just as valuable in the early- and midsummer border. The dark red blooms are like tiny posies surrounded by papery bracts, and the leaves are attractively lobed.

**H**: 36 in (90 cm); **S**: 18 in (45 cm)
❄❄❄ ◑ ☼ ◑

**Calamagrostis *x* acutiflora**
A strikingly erect grass with a strong winter presence. Popular cultivars include the arching, cream-striped 'Overdam' and the taller 'Karl Foerster', which in midsummer bears pinkish-brown plumes. In fall, both take on bronze or biscuit tones.

**H**: 5 ft (1.5 m); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ◑

**Centranthus ruber**
The red valerian is a drought-tolerant, fleshy-leaved self-seeder that blooms from late spring to late summer. The cone-shaped crimson flower clusters are great butterfly attractors. It benefits from deadheading. 'Albus' is white.

**H**: 36 in (90 cm); **S**: 36 in (90 cm)
❄❄❄ ◊ ☼

**Chelone obliqua**
This turtlehead is a hardy late-summer-flowering perennial that tolerates clay soil and occasional waterlogging. The upright flower stems bear curious pink blooms that open from tightly clustered buds. *Chelone leyonii* is similar but taller. Protect from slugs.

**H**: 24 in (60 cm); **S**: 12 in (30 cm)
❄❄❄ ◑ ● ☼ ◑

**Deschampsia cespitosa**
Varieties of the tufted hair grass, such as 'Goldschleier' (syn. 'Golden Veil'), form clumps of narrow, evergreen leaves that produce gracefully arching flower stems in early summer. The airy flowerheads catch the breeze and remain attractive well into fall.

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼ ◑

**Dryopteris affinis *'Cristata'***
Often referred to as the king of British ferns, this handsome cultivar has arching shuttlecocks of semi-evergreen fronds with frilled or crested tips. Surprisingly tolerant, it will withstand some sun and wind exposure. A good container plant.

**H**: 36 in (90 cm); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ☀

# Perennials and ornamental grasses

**Echinops ritro *'Veitch's Blue'***
Globe thistles are statuesque plants with coarse, deeply-toothed leaves and spherical, macelike flowerheads that are a magnet for bees, butterflies, and moths. This cultivar produces an abundance of steely blue blooms on upright, silvery stems.

**H**: 4 ft (1.2 m); **S**: 18 in (45 cm)
❄❄❄ ◊ ◑ ☼ ☀

**Eryngium *x* oliverianum**
One of the most ornamental of the sea hollies, from midsummer this hybrid has branching stems carrying abundant thimblelike heads of metallic blue, each with an elegant spiny "ruff." Although the blooms fade, they persist into fall.

**H**: 36 in (90 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ☼

**Euphorbia characias *'Humpty Dumpty'***
This compact, evergreen spurge blooms in spring, its chunky, acid-green flowerheads contrasting well with the gray-green foliage. Remove faded flower stems but avoid touching the sap, which may irritate the skin.

**H**: 24 in (60 cm); **S**: 20 in (50 cm)
❄❄❄ ◊ ☼

**Helictotrichon sempervirens**
Blue oat grass is evergreen and drought tolerant. In early and mid-summer, the tussocks of narrow, steely blue-gray leaves send up long stems carrying oatlike flowerheads. Use as a specimen in gravel or for massed plantings.

**H**: 4 ft (1.2 m); **S**: 24 in (60 cm)
❄❄❄ ◊ ☼

**Hemerocallis *'Corky'***
A free-flowering daylily that blooms from early to midsummer. Slender stems with dark buds produce a succession of starry yellow blooms with brown stripes on the back of the petals. Clumps of narrow, strap-shaped leaves appear in early spring.

**H**: 28 in (70 cm); **S**: 16 in (40 cm)
❄❄❄ ◑ ☼ ☀

**Iris foetidissima**
The stinking iris (its bruised leaves can smell unpleasant) has striking orange berries that burst from large pods in fall and remain attractive for weeks against the glossy, evergreen foliage. An invaluable plant for dry shade. 'Variegata' is white-striped.

**H**: 36 in (90 cm); **S**: 4 ft (1.2 m)
❄❄❄ ◊ ◑ ☼ ☀

**Iris sibirica *'Perry's Blue'***
Early-summer-flowering Siberian iris cultivars produce blooms in shades of blue, purple, and white and give a strongly vertical accent to the border. Their grassy foliage contrasts nicely with broadleaved plants and they have attractive seed pods.

**H**: 4 ft (1.2 m); **S**: 36 in (90 cm)
❄❄❄ ◑ ● ☼ ◑

**Knautia macedonica *Melton pastels***
This pincushion-flowered perennial bears blooms in shades of deep crimson through to pinks and purples. The loose tangle of branched stems creates a natural effect suitable for informal gardens. Deadhead regularly.

**H**: 4 ft (1.2 m); **S**: 20 in (50 cm)
❄❄❄ ◊ ☼

**Kniphofia *'Little Maid'***
An unusual and dainty red-hot poker that forms stiff, grassy clumps from which pale green flower buds appear in late summer and early fall. These expand to form pokers of pale yellow blooms that fade to cream. Protect flower buds from slugs.

**H**: 24 in (60 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ☼

**Leucanthemum *x* superbum**
The ubiquitous Shasta daisy tolerates a range of situations, including heavy clay, and will even hold its own in light grass cover. The long-stemmed white flowers emerge from a clump of leathery, dark green leaves from early summer to early fall.

**H**: 36 in (90 cm); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼ ◑

**Libertia grandiflora**
This architectural New Zealander produces handsome, fan-shaped tufts of olive-green leaves. In late spring and early summer, sprays of white flowers appear, followed by brown seed pods, which turn black as they mature. Mulch for winter.

**H**: 36 in (90 cm); **S**: 24 in (60 cm)
❄❄❄ ◑ ☼

**Lilium *'Enchantment'***
An easy, clump-forming lily, this is perfect planted near the front of the border. In early summer, the upright-facing, star-shaped blooms of bold orange open to reveal black-speckled centers. Add compost to sandy soils and watch out for lily beetles.

**H**: 24 in (60 cm); **S**: 6 in (15 cm)
❄❄❄ ◊ ◑ ☼ ◑

# Perennials and ornamental grasses

**Miscanthus sinensis *'Kleine Silbespinne'***
This compact ornamental grass with white-ribbed leaves is ideal for small gardens. In late summer, it is crowned with silky tufts of purple-tinged blooms that fade to white in fall and remain attractive into winter.

**H**: 4 ft (1.2 m); **S**: 36 in (90 cm)
❄❄❄ ◑ ☼ ◑

**Miscanthus sinensis *'Variegatus'***
Variegated with creamy-white stripes, this tall grass adds light and stature to the border. For small gardens, choose 'Morning Light', which reaches 4–5 ft (1.2–1.5 m) and has narrower blades with a fine white margin. Both bear red-brown flowers in late fall.

**H**: 6 ft (1.8 m); **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼ ◑

**Panicum virgatum *'Heavy Metal'***
The prairie switchgrasses are noted for their fall foliage tints and airy panicles. 'Heavy Metal' has upright clumps of metallic, blue-gray foliage, which begin turning yellow in fall. From late summer, plants have a halo of purple-tinged flowers.

**H**: 36 in (90 cm); **S**: 30 in (75 cm)
❄❄❄ ◑ ☼

**Penstemon *'Schoenholzeri'***
Narrow-leaved penstemons, like this free-flowering cultivar, are particularly hardy. These evergreen perennials produce a long succession of flowers from midsummer, especially if deadheaded regularly. Cut back to new leaf growth in spring.

**H**: 30 in (75 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Penstemon *'Stapleford Gem'***
This pretty, two-tone penstemon has broad leaves and an upright habit. The newer "bird" series has produced several excellent taller cultivars, such as 'Osprey', with pink and white blooms, the striking purple 'Raven', and the reddish-purple 'Blackbird'.

**H**: 24 in (60 cm); **S**: 18 in (45 cm)
❄❄❄ ◊ ◑ ☼

**Perovskia *'Blue Spire'***
Russian sage forms a clump of gray-green, toothed leaves. In late summer, wiry, branched, white stems carry tiny clusters of violet-blue flowers. A good dry garden specimen and bee magnet. The frosty-looking stems are attractive in winter.

**H**: 4 ft (1.2 m); **S**: 36 in (90 cm)
❄❄❄ ◊ ☼

**Phlomis russeliana**
This perennial's charm comes from the way the pale yellow flowers are arranged in ball-like clusters along the upright stems. The hooded blooms reach their peak in early summer but continue until early fall. Combine with other drought-tolerant plants.

**H**: 36 in (90 cm); **S**: 30 in (75 cm)
❄❄❄ ☼

**Rudbeckia fulgida *var.* deamii**
This black-eyed Susan provides vivid late summer and fall color with its golden, daisylike blooms, each with a dark, raised center. It is happy in heavy soil, and the dried flowers offer winter interest. *R. fulgida* var. *sullivantii* 'Goldsturm' is similar.

**H**: 24 in (60 cm); **S**: 18 in (45 cm)
❄❄❄ ◑ ☼ ◑

**Salvia *x* superba**
A hybrid sage, used most effectively in large swaths, which produces upright spires of glowing violet-purple flowers between midsummer and early fall. *S. nemorosa* 'Lubecca' and *S. verticillata* 'Purple Rain' are longer-flowering and more compact.

**H**: 36 in (90 cm); **S**: 18 in (45 cm)
❄❄❄ ◑ ☼

**Sedum *'Matrona'***
This fashionably dark-leaved sedum produces domed heads of tight buds that open to pink blooms in late summer, and form attractive seed-heads in fall. Both foliage and stems are a dusky purple. Divide every 3–4 years. Also try 'Herbstfreude' .

**H**: 24 in (60 cm); **S**: 24 in (60 cm)
❄❄❄ ☼ ◑

**Stipa gigantea**
Giant feather grass is an evergreen, tussock-forming species that, in summer, produces tall, arching stems with large, oatlike flowers. These are green at first, turning a glistening golden yellow with age. Excellent as a specimen or mingled with flowers.

**H**: 8 ft (2.5 m); **S**: 4 ft (1.2 m)
❄❄❄ ☼

**Verbena bonariensis**
Superb planted *en masse*, this tall-stemmed, elegant, self-seeding plant can be used toward the front of a border or beside paving. The many small, domed heads of violet flowers are produced from midsummer to fall and attract butterflies.

**H**: 6 ft (1.8 m); **S**: 18 in (45 cm)
❄❄ ☼

# Plant pruning guide (Ab–Ca)

**Abelia *x* grandiflora**
This *Abelia* is grown for its flowers or attractive variegated or gold foliage. In spring, prune out any stems with leaves that have lost their variegation. Usually requires little pruning except for leggy branches, and dead or damaged stems.

**H**: 10 ft (3 m); **S**: 12 ft (4 m)
❄❄ 💧 ☼

**Acer davidii**
The snakebark maple is famed for its bark, which provides wonderful winter interest. It is best grown on a single, clear trunk, which is achieved when the plant is small by removing the lower branches in summer or winter with pruning shears.

**H**: 50 ft (15 m); **S**: 50 ft (15 m)
❄❄❄ ◑ ☼ ◑

**Acer palmatum**
All cultivars are grown for their lovely foliage and fall colors. Prune leggy branches in midsummer to maintain a good shape. Remove any winter dieback in early spring and dead, diseased, or damaged branches when you see them.

**H**: 25 ft (8 m); **S**: 30 ft (10 m)
❄❄❄ ◑ ☼ ◑

**Actinidia deliciosa**
Kiwi fruit is a climber grown for its lovely foliage and fall colors. Prune leggy branches in midsummer to maintain a good shape. Remove any winter dieback in early spring and dead, diseased, or damaged branches when you see them.

**H**: 30 ft (10 m)
❄❄ 💧 ☼ ◑

**Artemisia '*Powis Castle*'**
This feathery shrub has attractive silver foliage that is lightly trimmed in spring to maintain its shape and to encourage growth. Give it a light shear as for lavender (*see p.344*), but do not cut back too hard or the plant will not rejuvenate.

**H**: 24 in (60 cm); **S**: 36 in (90 cm)
❄❄ 💧 ☼

**Aucuba japonica**
Grown for its glossy evergreen leaves, female plants can also bear attractive red berries, and many cultivars have decoratively spotted or variegated foliage. Prune plants lightly at any time to keep their shape; they also respond well to hard pruning.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ 💧 ◑ ☼ ◑ ●

**Berberis *x* stenophylla**
Grow this prickly gold-flowering plant as a freestanding shrub or hedge. If it gets too big, prune as for a mahonia (*see p.346*). To keep compact, after flowering remove one-third of the oldest stems and shorten leggy stems. Wear thick gloves.

**H**: 10 ft (3 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Berberis thunbergii**
Compact, with yellow flowers, bright red berries, and great fall color, this berberis has many uses. Wearing thick gloves, lightly prune in late summer or early fall to maintain its shape, or prune like a mahonia (*see p.346*) if it becomes too big.

**H**: 3 ft (1 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Betula utilis *var.* jacquemontii**
Grown for its attractive silvery-white bark. Remove the lower branches over several years as it matures. A trunk of 6 ft (2 m) is ideal for showing off the bark. Remove any damaged, diseased, or crossing branches from the canopy in midsummer or winter.

**H**: 60 ft (18 m); **S**: 30 ft (10 m)
❄❄❄ ◊ ◑ ☼ ◑

**Buddleja davidii**
The butterfly bush is a vigorous summer-flowering shrub. Prune it in late winter or early spring. Cut the branches back to two buds from the base of last season's growth. After flowering, also remove spent flowers to prevent them from seeding.

**H**: 10 ft (3 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Buxus sempervirens**
Often used as a small, formal hedge, this evergreen can also be trained into topiary shapes. When trained in either way, it is advisable to prune at least twice a year: once in late spring, and then again in midsummer.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Calluna vulgaris**
Common Scottish heather flowers during the summer months, and some cultivars have lovely golden foliage. For best results, it should be trimmed annually with shears in early spring, but don't cut back into old wood as the plant will not rejuvenate.

**H**: 4–24 in (10–60 cm); **S**: up to 30 in (75 cm) ❄❄❄ ◊ ☼

# Plant pruning guide (Ca–Ch)

**Camellia japonica**
This evergreen spring-flowering shrub does not require much pruning. To maintain its shape, branches may need trimming back after flowering. If the plant has grown too large, reduce and rejuvenate it by very hard pruning in summer.

**H**: 28 ft (9 m); **S**: 25 ft (8 m)
❄❄❄ ◑ ☼ ◑

**Camellia *x* williamsii '*Donation*'**
A spring-flowering evergreen shrub that is grown as a specimen plant or informal hedge. Remove leggy growths after flowering to maintain the plant's health. If it has grown too large, hard-prune to rejuvenate after flowering has finished.

**H**: 15 ft (5m); **S**: 8 ft (2.5 m)
❄❄❄ ◑ ☼ ◑

**Campsis *x* tagliabuana**
Train this vigorous exotic-looking climber, which flowers in the summer, up a wall, fence, or other permanent structure. To keep the plant at a manageable size, spur-prune each of the stems back to two pairs of buds in early spring.

**H**: 30 ft (10 m)
❄❄ ◊ ◑ ☼ ◑

**Carpinus betulus**
Hornbeam is a deciduous tree that can be used as either a freestanding ornamental plant or hedging. When grown as a tree, minimal pruning is required, but trim a hedge in late summer, or renovate old hedges in late winter).

**H**: 80 ft (25 m); **S**: 70 ft (20 m)
❄❄❄ ◊ ◑ ☼ ◑

**Caryopteris *x* clandonensis '*Arthur Simmonds*'**
This lovely small shrub has beautiful blue flowers in late summer and decorative, aromatic silver foliage. Prune it lightly in early spring, as for *Fuchsia magellanica* (*see p.341*).

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

**Catalpa bignonioides**
When grown as a tree, prune only to remove dead, diseased, and crossing stems. Alternatively, coppice young plants annually, to contain their size and encourage strong growths with extra-large, decorative leaves.

**H**: 50 ft (15 m); **S**: 50 ft (15 m)
❄❄❄ ◑ ☼

**Ceanothus '*Blue Mound*'**
This form of the evergreen California lilac flowers in early summer. A light pruning after flowering helps to limit the size of *Ceanothus*, but do not cut back into the old wood as plants don't normally regenerate.

**H**: 5 ft (1.5 m); **S**: 6 ft (2 m)
❄❄ ◊ ◑ ☼ ◑

**Ceratostigma willmottianum**
This wonderful little shrub has lovely blue flowers in the late summer. To prune, cut all the previous year's growths down to just above ground level in early to mid-spring. Mulch with garden compost and the plant will erupt into growth.

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ◑ ☼

**Cercis canadensis '*Forest Pansy*'**
A small tree that is grown for its early summer lilac-pink flowers and purple foliage, which turns vibrant red in the fall. Prune carefully when young to create a good branch structure. Thereafter, prune only if it becomes too large or branches get in the way.

**H**: 30 ft (10 m); **S**: 30 ft (10 m)
❄❄❄ ◊ ◑ ☼ ◑

**Chaenomeles *cultivars***
Grow flowering quinces as free-standing shrubs or train against a wall. Prune after flowering, cutting all new growths back to five or six buds. These will produce spurs covered in flowers the following spring. Also remove long or wayward branches.

**H**: up to 8 ft (2.5 m); **S**: up to 10 ft (3 m) ❄❄❄ ◊ ☼ ◑

**Chimonanthus praecox**
A highly scented, winter-flowering shrub whose flowers are produced from stems that are several years old, so prune just the leggy growths after flowering has finished. If it is too large, hard-prune in the winter, but it then will not flower for several years.

**H**: 12 ft (4 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ☼

**Choisya ternata**
The Mexican orange blossom is a flowering evergreen shrub. It requires little pruning, aside from removing in spring growths damaged by winter frosts. If the plant is looking untidy, it responds very well to hard pruning almost to ground level in early spring.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼

# Plant pruning guide (Cl–Co)

**Clematis alpina**
Violet-blue flowers appear in spring on last year's growth, followed by attractive fluffy seedheads. To prune, remove dead or damaged growths in early spring. For an overgrown plant, hard-prune to 6 in (15 cm) from the ground in early spring.

**H**: 6–10 ft (2–3 m), Group 1
❄❄❄ ◊ ◑ ☼ ☼

**Clematis armandii**
This evergreen clematis has large white, scented flowers. It is not fully hardy and prefers the shelter of a warm, sunny wall or fence. To prune, remove any growths in spring that have died or been damaged by cold winter weather.

**H**: 10–15 ft (3–5 m), Group 1
❄❄ ◊ ◑ ☼ ☼

**Clematis '*Etoile Violette*'**
A vigorous clematis that produces masses of purple flowers in late summer on its current year's growth. To prune, cut back all growths to 6–12 in (15–30 cm) above ground level in early spring.

**H**: 10–15 ft (3–5 m), Group 3
❄❄❄ ◊ ◑ ☼ ☼

**Clematis '*H.F. Young*'**
This clematis has large blue flowers in early summer. Prune lightly in early spring. From the top, prune each stem to the first pair of healthy buds. If the plant becomes too large, hard prune in early spring to 6 in (15 cm) above ground level.

**H**: 8 ft (2.5 m), Group 2
❄❄❄ ◊ ◑ ☼ ☼

**Clematis '*Jackmanii*'**
Producing masses of deep purple-blue flowers in summer on its current year's stems, this old favorite should be pruned in early spring. Cut back all growth to 6–12 in (15–30 cm) above ground level.

**H**: 10 ft (3 m), Group 3
❄❄❄ ◊ ◑ ☼ ☼

**Clematis '*Nelly Moser*'**
This popular clematis produces large pink flowers in late spring and again in late summer. Prune lightly in early spring, cutting each stem back to the first pair of healthy buds. Hard prune overgrown plants to 6 in (15 cm) from the ground in early spring.

**H**: 6–10 ft (2–3 m), Group 2
❄❄❄ ◊ ◑ ☼ ☼

**Cornus alba**
Dogwood is grown for its lovely winter stem colors and, of the many varieties, *C. alba* is a cheerful red. To encourage strong, colorful stems, prune in spring. If left unpruned, the stems start to lose their winter colors as they age.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ● ☼ ◑

**Cornus alternifolia '*Variegata*'**
This lovely shrub has white flowers in spring, and variegated leaves cover its tiered branches. To prune, remove lower branches of young plants for a more distinct shape, and occasionally thin the canopies of older trees to emphasize their horizontal structure.

**H**: 10 ft (3 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Cornus kousa *var.* chinensis**
The white bracts in late spring, red summer fruits, and fall leaves make this a valuable garden plant. In summer or winter, remove some lower branches on young plants so you can see the ornamental bark, and cut out crossing stems in the canopy.

**H**: 22 ft (7 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Cornus sanguinea '*Winter Beauty*'**
To produce multicolored stems during the winter, prune this plant in late spring to encourage strong growth. When young, it is best not to prune for two years to help it to establish; then prune annually.

**H**: 10 ft (3 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ● ☼ ◑

**Corylus avellana '*Contorta*'**
A slow-growing shrub with contorted stems, this hazel looks its best during the winter. In spring and summer, the branches are hidden under a mass of untidy leaves. Prune it only to remove any damaged, diseased, dead, or crossing branches.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

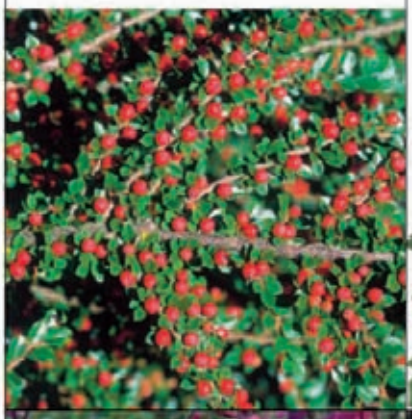
**Cotinus coggygria**
The smoke bush is grown for its colorful foliage and plumelike flowers. If left unpruned, it can become very large, so trim annually, but you may lose the flowers. For strong growth with larger leaves, hard-prune annually.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

# Plant pruning guide (Co–Eu)

**Cotoneaster horizontalis**
This low-growing shrub is excellent for covering walls and banks, and it is also suitable as ground cover. *Cotoneaster* has wonderful red berries in the fall. Prune in early spring to retain its shape and to prevent it from spreading too far.

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)
❄❄❄ 💧 ◑ ☼ ◑



**Crataegus monogyna**
The hawthorn is widely grown as an ornamental tree or as a hedging plant. It has scented flowers in late spring and is covered in red berries in fall. No pruning is required for a tree, but trim a hedge in early spring to reduce any wildlife disturbance.

**H**: 30 ft (10 m); **S**: 25 ft (8 m)
❄❄❄ 💧 ◑ ☼ ◑

**Cytisus *x* praecox**
This flowering broom is covered with golden yellow flowers in early summer. It requires minimal pruning, but can be given a light trim immediately after flowering to retain its shape. Do not cut back into the old wood as it will not regenerate.

**H**: 4 ft (1.2 m); **S**: 5 ft (1.5 m)
❄❄❄ 💧 ☼

**Daboecia cantabrica *f.* alba**
Give summer-flowering members of the heather family a light trim with a pair of shears in early spring. Remove all the old flowers, but don't be tempted to cut into the old wood as this will not regenerate.

**H**: 10–16 in (25–40 cm); **S**: 26 in (65 cm) ❄❄❄ 💧 ☼ ◑

**Daphne bholua**
The sweetly scented flowers of this shrub appear in winter. Pinch out the growing tips of young plants to encourage a bushy habit. This can also be done to older specimens, but do not hard-prune as the plant will not respond well.

**H**: 6–12 ft (2–4 m); **S**: 5 ft (1.5 m)
❄❄ 💧 ☼ ◑

**Deutzia *x* hybrida '*Mont Rose*'**
This lovely early summer-flowering shrub is easy to grow. Prune after flowering as for *Philadelphus* (*see p.347*), and aim to remove about one-third of the old stems to encourage new growths to push through from the base of the plant.

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄❄ 💧 ◑ ☼ ◑

**Elaeagnus pungens '*Maculata*'**
This evergreen with gold-splashed foliage is grown as a freestanding shrub or a hedge. Prune in winter or spring by cutting back the previous season's growth to two or three leaf buds. To avoid reversion, cut back all-green leaves to golden foliage.

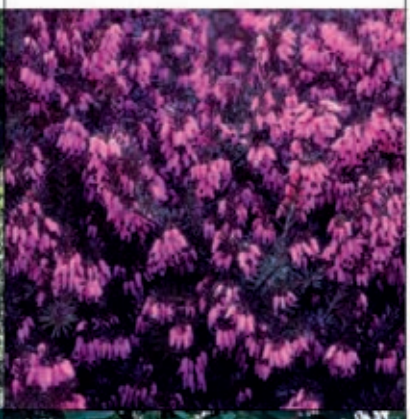
**H**: 12 ft (4 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ☼

**Erica arborea *var.* alpina**
The heather family includes many varieties, and this is one of the larger members. Tree heather produces masses of scented white flowers in the spring. Unlike other heathers, overgrown plants respond very well to hard pruning in mid-spring.

**H**: 6 ft (2 m); **S**: 34 in (85 cm)
❄❄❄ ◊ ☼

**Erica carnea**
This pretty winter-flowering member of the heather family should be pruned with shears in mid- to late spring. Remove the flowers, but do not cut into the old wood, as the plant will not regenerate.

**H**: 8–10 in (20–25 cm); **S**: 22 in (55 cm) ❄❄❄ ◊ ☼



**Erica cinerea *f.* alba**
The bell heather flowers from mid- to late summer. Trim in early spring using shears to remove the old flower spikes. Don't cut into old wood, as the plant will not regenerate.

**H**: 12 in (30 cm); **S**: 22 in (55 cm)
❄❄❄ ◊ ☼

**Escallonia '*Apple Blossom*'**
Grow this evergreen, early-summer-flowering shrub as a hedge or a freestanding plant. From mid- to late summer, cut back flowering shoots by one-half to keep the plant relatively compact. For plants that are too large, hard-prune after flowering.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼

**Eucalyptus gunnii**
This beautiful plant has distinctive silver-blue foliage. It can be allowed to grow into a large tree, but to keep it as a small bush, hard-prune annually in early spring. The resulting vibrantly colored young foliage also makes an excellent focal point.

**H**: to 80 ft (25 m); **S**: to 50 ft (15 m)
❄❄ ◊ ◑ ☼

# Plant pruning guide (Eu–Ha)

**Euonymus europaeus**
The spindle tree is grown for its fall colors and interesting fruits. Prune young trees to create a good shape and structure; older trees require little pruning aside from the removal of dead, damaged, or diseased wood and crossing stems.

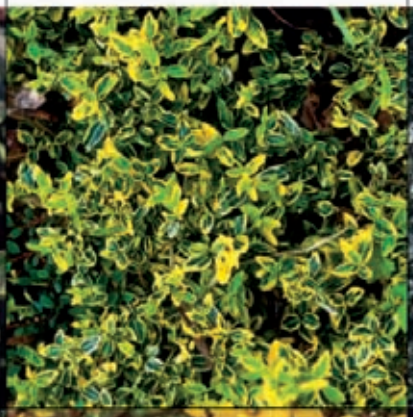
**H**: 10 ft (3 m); **S**: 8 ft (2.5 m)
❄❄❄ 💧 ◑ ☼ ◑

**Euonymus fortunei**
Train this evergreen foliage plant up a wall or fence, or grow it as ground cover or a freestanding shrub. Lightly trim in early spring to maintain a good shape. Remove immediately any reversion (stems with all-green foliage) on variegated forms.

**H**: 24 in (60 cm); **S**: indefinite
❄❄❄ 💧 ◑ ☼ ◑

**Exochorda *x* macrantha '*The Bride*'**
This pretty shrub has masses of white flowers in late spring. To maintain a young, vigorous plant, remove some of the oldest stems in spring. Hard-prune an overgrown plant in spring, but you will lose a year's flowering.

**H**: 6 ft (2 m); **S**: 10 ft (3 m)
❄❄❄ 💧 ◑ ☼ ◑



***x* Fatshedera lizei**
This evergreen shrub has large, shiny leaves similar in shape to ivy, and is suitable for shady areas. It is an excellent foliage plant and requires very little pruning apart from removing leggy growths. This is best done in the spring.

**H**: 4–6 ft (1.2–2 m); **S**: 10 ft (3 m)
❄❄ 💧 ◑ ☼ ◑

**Forsythia *x* intermedia '*Lynwood Variety*'**
The vivid yellow spring flowers of this large shrub appear on the previous season's branches. After flowering, remove annually one in three of the oldest branches. Hard-prune overgrown plants in early spring.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ 💧 ◑ ☼ ◑

**Fremontodendron '*California Glory*'**
This evergreen shrub is normally grown against a sunny wall. Occasionally, very long growths may need to be reduced in length in early summer. Be careful when pruning as the plant can cause skin irritation.

**H**: 20 ft (6 m); **S**: 12 ft (4 m)
❄❄ 💧 ☼

**Fuchsia magellanica**
An elegant summer-flowering plant, this fuchsia is grown as a freestanding shrub or a flowering hedge. In early spring, lightly trim the plant just back into green, healthy stems. After a severe winter, however, prune back to ground level.

**H**: 10 ft (3 m); **S**: 6–10 ft (2–3 m)
❄❄ 💧 ◑ ☼ ◑

**Garrya elliptica '*James Roof*'**
A large, slightly tender, evergreen shrub normally grown against a sunny wall for winter protection. It is covered with long, decorative, dangling catkins in winter that provide an exciting feature. Prune annually in early spring to contain its size.

**H**: 12 ft (4 m); **S**: 12 ft (4 m)
❄❄ 💧 ☼ ◑

**Gaultheria mucronata**
A dwarf evergreen, suckering shrub, *Gaultheria* is covered with very showy, waxlike fruits during the fall. Minimal pruning is required unless the plant is spreading too much and needs to be contained. This is best done in early spring.

**H**: 4 ft (1.2 m); **S**: 4 ft (1.2 m)
❄❄❄ ◑ ☼ ◑

**Genista aetnensis**
The Mount Etna broom is a large, graceful shrub with scented summer flowers. To keep it in shape and encourage flowering growths, prune lightly immediately after flowering. Do not cut back into old wood as the shrub will not regenerate.

**H**: 25 ft (8 m); **S**: 25 ft (8 m)
❄❄❄ 💧 ☼

**Griselinia littoralis**
This is an excellent evergreen that can be grown as a specimen shrub or a hedge. Trim hedges in late summer and freestanding shrubs in early spring if they become too large. Remove growths damaged by cold, frosty weather in early spring.

**H**: 25 ft (8 m); **S**: 15 ft (5 m)
❄❄❄ 💧 ☼

**Hamamelis *x* intermedia '*Pallida*'**
This is a scented late-winter- or early-spring-flowering shrub. It is suitable for a small garden if growth is kept in check. To do this, spur-prune previous year's growths to two or three buds after flowering (*see pp.172–173*).

**H**: 12 ft (4 m); **S**: 12 ft (4 m)
❄❄❄ 💧 ◑ ☼ ◑

# Plant pruning guide (He–Ja)

**Hedera helix**
Ivies are very versatile, self-clinging climbers. They will cover walls, fences, and trees, and also make good ground cover. When too large, prune back hard in spring to reduce the size. Trim at any time from late spring to midsummer to keep neat.

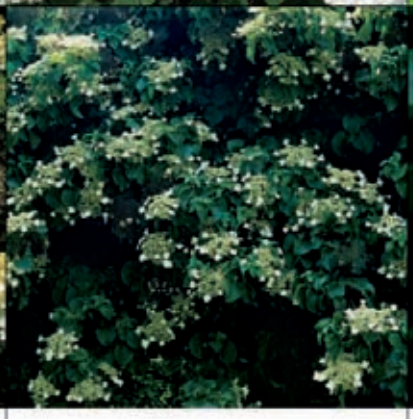
**H**: 30 ft (10 m)

**Hydrangea arborescens '*Grandiflora*'**
This summer-flowering hydrangea has large, creamy white flowerheads. It flowers on new growth and can be pruned like a perennial plant, cutting back to 2–4 in (5–10 cm) above ground level in early spring.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)

**Hydrangea macrophylla**
Florist's hydrangea flowerheads are produced on the previous season's growth. Leave them on the plant over winter to give frost protection. In mid-spring, cut back last year's growth to a pair of healthy buds and remove weak or dead shoots.

**H**: 6 ft (2 m); **S**: 8 ft (2.5 m)



**Hydrangea paniculata**
These hydrangeas produce large cone-shaped flowerheads on the current season's growth. To keep them small, prune all the previous season's stems back in early spring to two or three pairs of buds, to leave a low structure of stems.

**H**: 10–22 ft (3–7 m); **S**: 8 ft (2.5 m)

**Hydrangea petiolaris**
This self-clinging, climbing hydrangea requires little pruning. Remove growths that are too long in early spring, and old flowerheads after flowering. If the plant is too vigorous, prune hard in early spring, but it may then not flower for up to two years.

**H**: 50 ft (15 m)

**Hypericum '*Hidcote*'**
To keep this plant compact and producing masses of yellow summer flowers, remove dead or diseased wood in early spring and prune the remaining stems to 2–4 in (5–10 cm) from the ground. Also cut out one-third of older stems on large shrubs.

**H**: 4 ft (1.2 m); **S**: 5 ft (1.5 m)

**Ilex aquifolium '*Pyramidalis Aureomarginata*'**
This holly makes a bold, freestanding tree. It can also be trained into a formal shape or used as a hedge. Prune in early spring (all hollies tolerate severe pruning) and remove all-green foliage on sight.

**H**: 20 ft (6 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ☼

**Ilex crenata**
Box-leaved holly has small leaves and glossy black berries and makes an excellent clipped hedge or topiary plant. It is a suitable alternative to a boxwood hedge (*Buxus*) and is trimmed in the same way (*see p.169*).

**H**: 15 ft (5 m); **S**: 12 ft (4 m)
❄❄❄ ◊ ◑ ☼ ☼

**Indigofera heterantha**
This flowering shrub is covered with masses of pink, pealike flowers during the summer. Hard-prune large plants in early spring. In severe winters, it may suffer from dieback, but if hard-pruned, it will produce a mass of shoots from low down.

**H**: 6–10 ft (2–3 m); **S**: 6–10 ft (2–3 m) ❄❄❄ ◊ ◑ ☼

**Itea ilicifolia**
This evergreen shrub has masses of fingerlike stems of green flowers in the summer. It can be grown as a freestanding shrub or against a wall. When young, prune and pinch the plant to shape it in early spring. When older, just trim long growths.

**H**: 10–15 ft (3–5 m); **S**: 10 ft (3 m)
❄❄ ◊ ◑ ☼

**Jasminum nudiflorum**
The winter jasmine produces bright yellow flowers over a long period throughout winter and early spring. It is normally trained against a wall or fence. Prune long, leggy growths immediately after it has finished flowering in early spring.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼ ☼

**Jasminum officinale**
Common jasmine has white, scented flowers in the summer. It is a vigorous climber and can be trained up walls or over other structures. Trim at any time to keep the plant within bounds. Hard-prune plants that have grown too large in early spring.

**H**: 40 ft (12 m)
❄❄ ◊ ◑ ☼ ☼

# Plant pruning guide (Ke–Lu)

**Kerria japonica '*Golden Guinea*'**
A clump-forming suckering shrub covered with large, golden flowers in late spring, *Kerria* can soon outgrow its situation. To contain its size, prune it hard or thin out old stems after flowering each year.

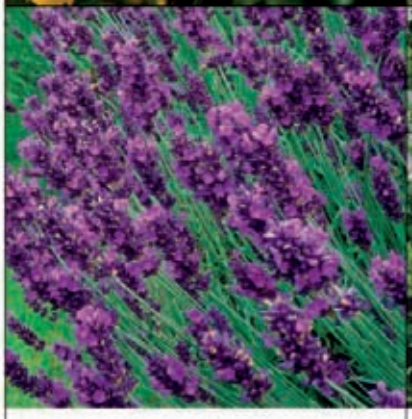
**H**: 6 ft (2 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ☼

**Kolkwitzia amabilis '*Pink Cloud*'**
The beauty bush is a large shrub with pendulous branches covered in pink flowers in late spring. Prune it after flowering, removing about one-third of the old flowering stems. Cut back large plants in early spring to 12 in (30 cm) above the ground.

**H**: 10 ft (3 m); **S**: 12 ft (4 m)
❄❄❄ ◊ ◑ ☼

**Laurus nobilis**
Bay laurel is an evergreen shrub that can be trained into many formal shapes and makes an excellent topiary specimen. Prune formal and topiary plants during early summer, but use pruning shears to shape them.

**H**: 40 ft (12 m); **S**: 30 ft (10 m)
❄❄ ◊ ◑ ☼ ☼



**Lavandula angustifolia**
This lavender is a mass of blue-purple aromatic flowers during the summer. It makes an excellent low-growing hedge. For best results, prune twice a year: shear back in early spring and then trim lightly once it has finished flowering.

**H**: 3 ft (1 m); **S**: 4 ft (1.2 m)
❄❄❄ ◊ ☼

**Lavatera x clementii '*Barnsley*'**
Mallow is a shrubby perennial that produces an abundance of large, pale pink summer flowers. To keep a plant young and healthy, prune in spring to a framework of strong stems about 12 in (30 cm) high. Also remove any dead, diseased, or weak branches.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄❄ ◊ ☼

**Lespedeza thunbergii**
A lovely late summer-flowering shrubby perennial, bush clover has arching stems covered in deep pink, pealike flowers. Prune back all the stems in spring to just above ground level and new young shoots will quickly appear.

**H**: 6 ft (2 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ☼

**Leycesteria formosa**
This shrub has white flowers surrounded by maroon bracts during the summer, followed by purple berries. It is almost indestructible and can be left unpruned, or it grows just as well if it is hard-pruned every year in early spring.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄❄ 💧 ◑ ☼ ◑

**Ligustrum lucidum**
The panicles of white flowers on this evergreen shrub appear during late summer. It has a lovely, even shape and requires minimal pruning. Occasionally, it may be necessary to trim a few of the branches to maintain its shape.

**H**: 30 ft (10 m); **S**: 30 ft (10 m)
❄❄❄ 💧 ☼ ◑

**Lonicera nitida**
This form of evergreen honeysuckle is often used as a hedging plant or a shrub. When grown as a hedge, trim it several times in the summer to maintain its shape. For a free-standing shrub, remove about a third of the older stems in early spring.

**H**: 11 ft (3.5 m); **S**: 10 ft (3 m)
❄❄❄ 💧 ◑ ☼ ◑

**Lonicera periclymenum '*Graham Thomas*'**
If it's a highly scented summer-flowering climber that you are after, this is the plant for you. If it becomes straggly, prune in early spring. Also remove any dead or damaged wood at this time.

**H**: 22 ft (7 m)
❄❄❄ 💧 ◑ ☼ ◑

**Lonicera *x* purpusii**
This shrubby honeysuckle is grown for its creamy white, highly scented winter flowers. To keep the plant to a manageable size, remove one-third of the old stems to almost ground level in early spring.

**H**: 6 ft (2 m); **S**: 8 ft (2.5 m)
❄❄❄ 💧 ☼ ◑

**Luma apiculata**
An evergreen shrub or small tree grown for its attractive peeling bark and small white flowers, which appear in late summer. As it grows, remove some of the lower branches in the summer so that you can fully appreciate the wonderful bark.

**H**: 30–50 ft (10–15 m); **S**: 30–50 ft (10–15 m) ❄❄ 💧 ☼ ◑

# Plant pruning guide (Ma–Ph)

**Magnolia grandiflora**
Grow this lovely evergreen, summer-flowering tree against a south-facing wall, and prune in the spring or summer to maintain its shape. Pruning reduces the chance of die-back and allows the wounds to heal before the cold winter months set in.

**H**: 20–60 ft (6–18 m); **S**: 50 ft (15 m)

**Magnolia x loebneri '*Leonard Messel*'**
This spring-flowering tree requires minimal pruning. When it is young, you may need to remove a few lower branches in the spring or summer to give it a good shape. As it gets older, cut back any obstructive branches.

**H**: 25 ft (8 m); **S**: 20 ft (6 m)

**Mahonia aquifolium**
An evergreen suckering shrub that flowers in the winter and makes good ground cover. To keep Oregon grape at a reasonable size, cut it down to ground level every three or four years after flowering, or remove one-third of the oldest stems every year.

**H**: 3 ft (1 m); **S**: 3 ft (1 m)

**Mahonia x media '*Charity*'**
If this evergreen, winter-flowering shrub has outgrown its site, hard-prune in early spring. To keep it in good shape, shorten leggy growths in early spring and remove flowering shoots to encourage growth from lower down.

**H**: to 15 ft (5 m); **S**: to 12 ft (4 m)

**Malus '*Golden Hornet*'**
When this flowering and fruiting ornamental crab apple is young, remove lower branches in winter to encourage a good shape. On an older tree, remove dead or diseased wood immediately, and cut off any branches causing an obstruction.

**H**: 30 ft (10 m); **S**: 25 ft (8 m)

**Malus hupehensis**
This is an ornamental flowering and fruiting apple tree. When it is young, remove lower branches in winter to encourage a good shape. Remove dead or diseased branches on old plants at any time, and cut off any others that are out of place.

**H**: 40 ft (12 m); **S**: 40 ft (12 m)

**Nandina domestica**
This evergreen, clump-forming shrub has white flowers during the summer followed by berries in the fall. It requires minimal pruning to maintain its shape—remove the oldest stems in the summer. Over-pruning reduces the number of flowers produced.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)
❄❄ ◊ ◑ ☼

**Olearia stellulata**
The daisy bush is a compact, free-flowering evergreen shrub that is covered in white flowers in late spring. Hard-prune leggy, untidy specimens immediately after flowering has finished.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄ ◊ ☼

**Osmanthus heterophyllus '*Variegatus*'**
An evergreen compact shrub with small, fragrant white flowers and hollylike leaves, used for hedging or topiary. Prune hedges in late spring or early summer, and clip topiary in the summer.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄ ◊ ☼ ◑

**Parthenocissus tricuspidata**
Boston ivy is a vigorous, self-clinging climber that is grown for its attractive fall foliage colors, which range from brilliant red to purple. Prune in spring before it comes into leaf or in fall after leaf drop to maintain its shape and keep it in check.

**H**: 70 ft (20 m)
❄❄❄ ◊ ◑ ☼ ◑

**Perovskia '*Blue Spire*'**
This is an attractive compact shrub with blue flowers in the late summer and attractive silvery foliage. Prune annually in spring, cutting back the stems to 6 in (15 cm) to encourage strong growths, which will flower during the forthcoming summer.

**H**: 4 ft (1.2 m); **S**: 3 ft (1 m)
❄❄❄ ◊ ☼

**Philadelphus**
Mock orange is grown for its white, highly scented flowers, which appear in early summer. Hard-prune the shrub to 6 in (15 cm) in early spring every three or four years, or remove one-third of the oldest stems annually after flowering.

**H**: to 10 ft (3 m); **S**: to 8ft (2.5m)
❄❄❄ ◊ ◑ ☼ ◑

# Plant pruning guide (Ph–Rh)

**Photinia *x* fraseri '*Red Robin*'**
An evergreen shrub that has attractive bright red new growths and can be grown as a freestanding shrub or decorative hedge. If grown as a hedge, trim in late summer; a freestanding plant should be shaped in early spring.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Phygelius *x* rectus '*African Queen*'**
This plant has long, tubular, orange flowers during the summer. To prevent the plant from becoming leggy, treat it like a perennial, cutting back all the stems to almost ground level in the spring.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m)
❄❄ ◊ ◑ ☼

**Physocarpus opulifolius '*Dart's Gold*'**
An attractive clump-forming shrub with bright yellow new foliage, it produces white flowers in early summer. Little pruning is required, except to remove any of the outer stems that are spoiling its shape.

**H**: 6 ft (2 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼ ◑

**Pittosporum tenuifolium**
Many of the forms of this evergreen shrub have variegated foliage and it makes an attractive formal focal point. The only pruning required is to retain the plant's symmetry by lightly trimming it in late spring.

**H**: 12–30 ft (4–10 m); **S**: 6–15 ft (2–5 m) ❄❄ ◊ ◑ ☼ ◑

**Potentilla fruticosa '*Goldfinger*'**
An attractive small shrub with golden flowers during the summer, this pretty shrubby potentilla requires just a light trim in early spring to maintain its rounded shape.

**H**: 3 ft (1 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ☼

**Prunus avium '*Plena*'**
This ornamental cherry has large white flowers in mid-spring. Prune in early summer to reduce the risk of infection. Remove dead, diseased, or crossing branches. Young trees should be pruned at the same time.

**H**: 40 ft (12 m); **S**: 40 ft (12 m)
❄❄❄ ◊ ◑ ☼

**Prunus laurocerasus**
Cherry laurel is an evergreen with glossy green leaves. Prune freestanding shrubs in early spring to reduce their size, and a hedge in early fall. Use pruning shears to avoid shredding the leaves. Prune overgrown plants to just above the ground in spring.

**H**: 25 ft (8 m); **S**: 30 ft (10 m)
❄❄❄ 💧 ◑ ☼ ☀

**Prunus mume**
This attractive, early flowering ornamental cherry blossoms on last year's shoots. In early summer, reduce the length of all main branches by 12 in (30 cm) to encourage new growths, which will be covered in flowers the following spring.

**H**: 28 ft (9 m); **S**: 28 ft (9 m)
❄❄❄ 💧 ◑ ☼

**Prunus serrula**
The attractive mahogany-red bark on this ornamental cherry makes an eye-catching feature in winter. In early summer, remove the lower branches of a young tree to give at least 6 ft (1.8 m) of clear trunk. Remove dead and diseased branches as seen.

**H**: 30 ft (10 m); **S**: 30 ft (10 m)
❄❄❄ 💧 ◑ ☼

**Pyracantha '*Orange Glow*'**
Firethorn is an evergreen shrub or small tree grown for its orange fall and winter fruits. It can be grown against a wall, as a hedge, or as a freestanding shrub. Prune in spring to maintain its shape, taking care not to remove flower buds.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ 💧 ☼ ◑ ☀

**Pyrus salicifolia *var.* orientalis '*Pendula*'**
This attractive silver-leaved weeping pear has creamy-white flowers and small brown, inedible fruits. Remove the lower branches of a young tree in winter to create a clear stem for the weeping branches to cascade down.

**H**: 15 ft (5 m); **S**: 12 ft (4 m)
❄❄❄ 💧 ☼

**Rhamnus alaternus '*Argenteovariegata*'**
Prune this fast-growing evergreen shrub in early spring to remove any leggy growths and to maintain the shape of the bush. If any stems with all-green leaves appear, remove them without delay.

**H**: 15 ft (5 m); **S**: 12 ft (4 m)
❄❄ 💧 ☼

# Plant pruning guide (Rh–Ro)

**Rhamnus frangula (*syn.* Frangula alnus '*Aspleniifolia*')**
In the fall, alder buckthorn has attractive yellow foliage and ornamental berries. The shrub responds well to being hard-pruned to almost ground level every three or four years.

**H**: 10–12 ft (3–4 m); **S**: 6–10 ft (2–3 m) ❄❄❄ ◑ ☼ ◑

**Rhododendron luteum**
This deciduous, clump-forming azalea is grown for its attractive yellow, scented flowers in early summer and its fall foliage color. It normally requires very little pruning, but you can hard-prune overgrown plants to almost ground level in early spring.

**H**: 12 ft (4 m); **S**: 12 ft (4 m) ❄❄❄ ◑ ☼ ◑

**Rhododendron *Nobleanum Group***
Most hybrid rhododendrons require little or no pruning, although plants that have rough bark, such as those in the Nobleanum Group, can be pruned in early spring if they are too large. They will regenerate.

**H**: 15 ft (5 m); **S**: 15 ft (5 m) ❄❄❄ ◑ ☼ ◑

**Rhododendron '*Rose Bud*'**
This attractive evergreen azalea normally requires very little pruning. However, it can be trained into formal shapes and also makes an attractive, low-growing hedge. In early summer, after flowering has finished, lightly trim with shears.

**H**: to 36 in (90 cm); **S**: to 36 in (90 cm) ❄❄❄ ◑ ☼

**Rhus typhina**
A deciduous shrub or small tree, the staghorn sumac has attractive divided foliage, which turns a brilliant orange-red in the fall. Hard-prune it in early spring to keep compact: cut the stems back to between 12–24 in (30–60 cm) from the ground.

**H**: 15 ft (5 m) or more; **S**: 20 ft (6 m) ❄❄❄ ◑ ☼

**Ribes sanguineum '*Pulborough Scarlet*'**
The stems of this ornamental currant bear masses of dark red, white-centered flowers in spring. To contain the plant's size and vigor, remove one-third of the oldest stems annually immediately after flowering.

**H**: 10 ft (3 m); **S**: 8 ft (2.5 m) ❄❄❄ ◑ ☼ ◑

**Ribes speciosum**
This currant is normally grown and trained against a wall or fence, and has beautiful red flowers from mid- to late spring. Remove one-third of the older stems immediately after flowering and tie the remaining stems to the wall or support.

**H**: 6 ft (2 m); **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ☀

**Robinia pseudoacacia '*Frisia*'**
The main feature of this deciduous tree is its golden foliage. To produce a small golden shrub, coppice young plants every spring (*see pp.158–159*). Do not prune large trees except to remove dead or diseased wood as the wounds heal slowly.

**H**: 50 ft (15 m); **S**: 25 ft (8 m)
❄❄❄ ◊ ◑ ☼

**Rosa *Baby Love***
This patio rose is grown for its single, clear yellow summer flowers. Prune in early spring, cutting the stems back by one-half to encourage flowering growths (*see pp.186–187*). Also remove any dead or diseased stems and crossing growths.

**H**: 3½ ft (1.2 m); **S**: 30 in (75 cm)
❄❄❄ ◊ ◑ ☼

**Rosa '*Climbing Iceberg*'**
Prune climbing roses in fall or early spring. Remove the oldest stems and spur-prune the previous season's flowering growths to two or three buds to encourage more flowers in early summer (*see also pp.214–215*). Tie in any strong new stems.

**H**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼

**Rosa '*Crimson Shower*'**
Grow this rambling rose for its rich red flowers. If trained on a support, remove some of the oldest canes in early spring and spur-prune (*see pp.172–173*). When trained through a tree, you only need to cut out dead or diseased growth.

**H**: 8 ft (2.5 m); **S**: 7 ft (2.2 m)
❄❄❄ ◊ ◑ ☼

**Rosa '*Félicité Parmentier*'**
This is a lovely scented, old-fashioned shrub rose. Prune in early spring, reducing the height of the plant by cutting back the main stems by one-quarter, and lightly trimming the side-shoots (*see pp.188–189*). Remove any dead, diseased, and crossing stems.

**H**: 4½ ft (1.3 m); **S**: 4 ft (1.2 m)
❄❄❄ ◊ ◑ ☼

# Plant pruning guide (Ro–Sa)

**Rosa glauca**
This rose is mainly grown for its attractive blue-green foliage. To keep it tidy and to encourage strong young growths, prune in early spring by removing one-third of the older stems. Hard-prune overgrown plants to about 6 in (15 cm) from ground level.

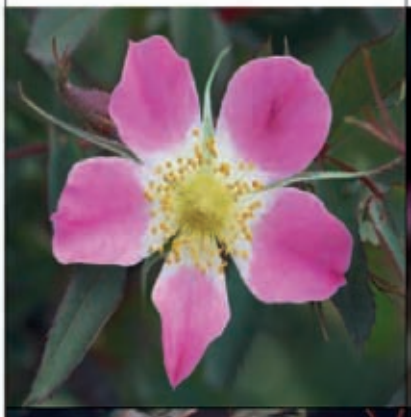
**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ◑ ☼

**Rosa *Lovely Lady***
A hybrid tea rose with salmon-pink scented flowers, Lovely Lady is pruned in early spring like other hybrid tea roses. Remove all but three or four older growths, and cut these back to about 6 in (15 cm), ideally to an outward-facing bud.

**H**: 30 in (75 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Rosa mulliganii**
Covered with white, scented flowers in the summer and red hips in the fall, this rose will climb up supports or into trees. Remove the oldest canes in early spring and spur-prune lateral growths to three buds to encourage flowers.

**H**: 20 ft (6 m)
❄❄❄ ◊ ◑ ☼



**Rosa *Paul Shirville***
The dark reddish-green foliage of this hybrid tea rose contrasts beautifully with its fragrant rose-pink flowers, which appear from summer to fall. Prune as for Lovely Lady (*above*).

**H**: 3 ft (1 m); **S**: 30 in (75 cm)
❄❄❄ ◊ ◑ ☼

**Rosa *Queen Elizabeth***
Queen Elizabeth is a pink-flowered floribunda rose that blooms from summer to fall. Prune in early spring, leaving 6 or 8 strong stems. Cut these back to about 8–12 in (20–30 cm) from the ground, to an outward-facing bud if possible.

**H**: 7 ft (2.2 m); **S**: 3 ft (1 m)
❄❄❄ ◊ ◑ ☼

**Rosa *Queen Mother***
Prune this floriferous, pale-pink-flowered patio rose in early spring. Prune all the stems back by about one-half to encourage lots of flowering growths. Also remove dead or diseased stems, and any crossing growths.

**H**: 16 in (40 cm); **S**: 24 in (60 cm)
❄❄❄ ◊ ◑ ☼

**Rosa rugosa**
This species rose has thorny stems and red, richly perfumed flowers from summer to fall. It makes an effective hedging plant and requires minimal pruning aside from removing one or two of the oldest stems each year in late winter or early spring.

**H**: 3–8 ft (1–2.5 m); **S**: 3–8 ft (1–2.5 m) ❄❄❄ ◊ ◑ ☼

**Rosa '*Sally Holmes*'**
"Sally Holmes" is a modern shrub rose that flowers from summer to fall and needs to be pruned in early spring. Reduce its height by one-quarter and remove any dead, diseased, or crossing stems and any weak, twiggy growths.

**H**: 6 ft (2 m); **S**: 3 ft (1 m) ❄❄❄ ◊ ◑ ☼

**Rosa *Trumpeter***
Like Queen Elizabeth (*facing page*), this rose is a floribunda. It is appreciated for its clusters of vivid orange-red flowers that brighten up beds and borders from summer to fall. Prune as for Queen Elizabeth.

**H**: 24 in (60 cm); **S**: 20 in (50 cm) ❄❄❄ ◊ ◑ ☼

**Rosmarinus officinalis**
This aromatic herb has small, silvery evergreen leaves and blue flowers in late spring. Old plants do not respond well to hard pruning and are best replaced. Shear young plants in early summer after the flowers have faded to maintain an even shape.

**H**: 5 ft (1.5 m); **S**: 5 ft (1.5 m) ❄❄ ◊ ◑ ☼

**Rubus cockburnianus**
Grow this thorny decorative bramble for its winter interest, when the stems are covered in brilliant white bloom. Prune to almost ground level annually in early spring to encourage strong growths. Take care when cutting this shrub because the thorns are vicious.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m) ❄❄❄ ◊ ☼

**Salix alba *var.* vitellina '*Britzensis*'**
The orange-yellow stems make this form of white willow a must for winter interest. Coppice or pollard all shoots, first removing weak, dead, or diseased growth, to two or three pairs of healthy buds.

**H**: 80 ft (25 m) if unpruned; **S**: 30 ft (10 m) ❄❄❄ ◊ ◑ ● ☼

# Plant pruning guide (Sa–Sy)

**Salix daphnoides**
Violet willow is grown for winter interest when the stems are covered in white blooms. Gray catkins follow. Prune hard in spring, cutting strong branches back to two or three pairs of buds from the ground. Remove all weak, dead, or diseased stems.

**H**: 25 ft (8 m); **S**: 20 ft (6 m)
❄❄❄ 💧 ◑ ☼

**Sambucus nigra '*Aurea*'**
This ornamental elder is grown for its white flowers, ornamental fruit, and golden yellow leaves. Prune annually in early spring—cut back all its stems to two or three buds of the previous year's growth, to leave a structure similar to *Cotinus* (*see p.337*).

**H**: 20 ft (6 m); **S**: 20 ft (6 m)
❄❄❄ 💧 ◑ ☼ ◑

**Santolina chaemaecyparissus**
Aromatic gray foliage and bright yellow pompon flowers in the summer define this shrub. It can be grown as a low hedge or edging plant and also on its own. Trim over in spring using shears in a similar fashion to lavender (*see p.344*).

**H**: 20 in (50 cm); **S**: 3 ft (1 m)
❄❄ 💧 ☼

**Schizophragma hydrangeoides**
This vigorous, self-clinging climber produces fragrant, creamy-white, flat-topped flowerheads in midsummer, which are set off by the dark green leaves. Its pruning requirements are the same as for *Hydrangea petiolaris* (*see p.342*).

**H**: 40 ft (12 m)
❄❄❄ 💧 ◑ ☼ ◑

**Skimmia japonica '*Nymans*'**
A useful evergreen shrub with scented flowers that appear in mid- to late spring followed by red berries. It requires minimal pruning aside from occasionally shortening some shoots to maintain its shape.

**H**: 20 ft (6 m); **S**: 20 ft (6 m)
❄❄❄ 💧 ◑ ◑ ●

**Solanum crispum '*Glasnevin*'**
The Chilean potato tree is a vigorous, slightly tender climber grown for its scented, purple-blue summer flowers. It requires minimal pruning, but can be cut back in spring if it has outgrown its location.

**H**: 20 ft (6 m)
❄❄ 💧 ◑ ☼

**Sorbus commixta**
A small, upright tree grown for its fall foliage color and red berries. Sorbus trees require little pruning aside from shaping young specimens in early summer. Remove any dead or diseased branches as soon as you see them.

**H**: 30 ft (10 m); **S**: 22 ft (7 m)
❄❄❄ ◊ ◑ ☼ ☀

**Spiraea japonica**
This is a small, deciduous clump-forming shrub with pink or white flowers that appear from mid- to late summer. It flowers on the current year's growth, so hard-prune in early spring if required.

**H**: 6 ft (2 m); **S**: 5 ft (1.5 m)
❄❄❄ ◊ ◑ ☼

**Spiraea nipponica '*Snowmound*'**
A fast-growing shrub, with white midsummer flowers that appear on shoots formed the previous year. To encourage these shoots, cut back one-third of the older stems to the base of the plant immediately after flowering.

**H**: to 8 ft (2.5 m); **S**: to 8 ft (2.5 m)
❄❄❄ ◊ ◑ ☼

**Stachyurus '*Magpie*'**
A variegated shrub that produces pendulous stems of creamy yellow flowers in spring. It can be grown on its own or against a wall. Freestanding plants require no pruning, while those grown as wall shrubs can be pruned to shape after flowering.

**H**: 3–12 ft (1–4 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼ ☀

**Stewartia pseudocamellia**
White flowers in summer and good fall foliage color distinguish this tree. It also has ornamental bark, which can be enjoyed by removing young lower branches in early spring to achieve a clear stem of up to 6 ft (1.8 m). No other pruning is required.

**H**: 70 ft (20 m); **S**: 25 ft (8 m)
❄❄❄ ◑ ☼ ☀

**Syringa vulgaris**
Lilac trees offer richly scented flowers from late spring to early summer. They grow without pruning, but if plants need containing, they tolerate being cut back hard every year after flowering, when some of the oldest growths can be removed.

**H**: 22 ft (7 m); **S**: 22 ft (7 m)
❄❄❄ ◊ ◑ ☼

# Plant pruning guide (Ta–Wi)

**Tamarix parviflora**
Tamarisk is a delightful small tree with fine green foliage and masses of small pink flowers in late spring. As the plant ages, it becomes messy and needs pruning to maintain its shape. It flowers on the previous year's growth, so prune after flowering.

**H**: 15 ft (5 m); **S**: 20 ft (6 m)
❄❄❄ 💧 ◑ ☼

**Tamarix ramosissima '*Pink Cascade*'**
This form of tamarisk has fine green foliage and masses of rich, pink, airy flowers, which form on new shoots from late summer to early fall. Prune in early spring, cutting back stems to maintain its shape.

**H**: 15 ft (5 m); **S**: 15 ft (5 m)
❄❄❄ 💧 ◑ ☼

**Taxus baccata**
Yew is an evergreen conifer that can be used as a hedging plant or topiary specimen, or trained into formal shapes. Prune yew hedges in late summer, and trim topiary and formal-shaped specimens in summer.

**H**: to 70 ft (20 m); **S**: to 30 ft (10 m)
❄❄❄ 💧 ☼ ◑ ●

**Tilia cordata '*Winter Orange*'**
This linden tree has bright yellow foliage in the fall. It can ultimately become a large tree, but with careful training it is ideal for pleaching. Prune to shape in the winter.

**H**: 90 ft (25 m); **S**: 50 ft (15 m)
❄❄❄ 💧 ◑ ☼ ◑

**Toona sinensis '*Flamingo*'**
A clump-forming tree grown for its bright pink new foliage, *Toona* also has white flowers in late summer and attractive fall tints. Remove any frost-damaged growths in late spring, and hard-prune large plants in spring, cutting back to almost ground level.

**H**: 50 ft (15 m); **S**: 30 ft (10 m)
❄❄❄ 💧 ☼

**Trachelospermum jasminoides**
An evergreen climber with sweetly scented white flowers during the summer, star jasmine prefers to grow against a sheltered wall. No routine annual pruning is required, but you can reduce its height by pruning in late spring.

**H**: 28 ft (9 m)
❄❄ 💧 ☼ ◑

**Viburnum *x* bodnantense '*Dawn*'**
Grown for it scented pink flowers that are produced during the fall and early winter, this shrub can be left unpruned to become a large plant or kept small in size by removing one-fifth of the oldest stems to ground level in early spring.

**H**: 10 ft (3 m); **S**: 6 ft (2 m)
❄❄❄ ◊ ◑ ☼ ◑

**Viburnum tinus '*Eve Price*'**
This evergreen shrub is grown for its white flowers, which are produced from fall to early spring. It does not require routine annual pruning, but remove damaged or diseased growths when seen. Hard-prune overgrown plants in early spring.

**H**: 10 ft (3 m); **S**: 10 ft (3 m)
❄❄❄ ◊ ◑ ☼ ◑

**Vitex agnus-castus *var.* latifolia**
The chaste tree is a deciduous shrub with attractively divided foliage that sets off the spikes of lilac- to dark blue late summer flowers. Prune the previous year's growths back to two or three buds in early spring.

**H**: 6–25 ft (2–8 m); **S**: 6–25 ft (2–8 m) ❄❄ ◊ ☼

**Vitis vinifera '*Purpurea*'**
In fall or early winter, cut back this vigorous climbing grape. Spur-prune all side stems to two buds from the previous season's growth to leave short, stubby growths on either side of the main stem. Shorten overly long stems in summer.

**H**: 22 ft (7 m)
❄❄❄ ◊ ◑ ☼

**Weigela florida**
A deciduous shrub grown for its tubular dark pink flowers that appear mainly from late spring to early summer. To prune, thin out and remove one-third of the oldest growths immediately after flowering in the summer.

**H**: 8 ft (2.5 m); **S**: 8 ft (2.5 m)
❄❄❄ ◊ ☼ ◑

**Wisteria sinensis**
*Wisteria* is a vigorous climber that produces long, scented chains of flowers in late spring. In the winter, spur-prune all the summer's growth back to two buds. During the summer, shorten long, leggy stems by up to two-thirds.

**H**: 28 ft (9 m) or more
❄❄❄ ◊ ◑ ☼ ◑

# Pruning calendar: spring

## Trees to prune

Evergreens, such as *Magnolia grandiflora* and holly (*Ilex*), prefer to be pruned at this time of year, but most other trees are best pruned in summer or winter. In particular, avoid pruning trees that bleed sap profusely, such as birch (*Betula*) and walnut (*Juglans*), from mid-spring onward.

## Shrubs to prune

Prune winter-flowering shrubby honeysuckles, such as *Lonicera fragrantissima* and *Lonicera standishii*. In mid-spring, cut back heather (*Erica*), *Buddleja davidii*, early-flowering *Camellia*, witch hazel (*Hamamelis*), *Mahonia*, winter-flowering viburnum (*Viburnum* x *burkwoodii*), dogwood (*Cornus*), willow (*Salix*), and *Rubus*. In late spring, prune hydrangeas and, after flowering, forsythia.

## Climbers to prune

Prune clematis in Groups 2 and 3 in the spring, plus any long, wayward stems of climbing hydrangeas (*Hydrangea petiolaris*), and any climbing or rambling roses you missed in fall. Also trim climbing honeysuckles (*Lonicera*), *Jasminum nudiflorum*, and overgrown ivy (*Hedera*).

## Hedge care

In late winter or early spring, renovate hornbeam (*Carpinus*), beech (*Fagus*), yew (*Taxus*), and holly (*Ilex*) hedges, and prune wildlife hedges before birds begin to nest. Pruning the latter also ensures that plants develop plenty of flowering shoots and, later, fall berries for wildlife. Prune lavender (*Lavandula*) in mid-spring.

Prune mahonias after flowering.

Renovate hornbeam and beech hedges in early spring.

## Main pruning tasks

Spring is a busy time for pruning jobs. The sap is rising and buds are swelling, which means that plants are more likely to recover from a haircut.

The main pruning tasks in the spring are cutting back shrubs with winter stem interest, such as dogwood (*Cornus*), willow (*Salix*), and decorative bramble (*Rubus*).

Follow this by pruning floribunda, hybrid tea, and shrub roses. You can also still prune climbing and rambler roses now if you didn't have time in the fall.

As there are no leaves on most deciduous trees and shrubs at this time of year, you can clearly see and cut out wood damaged in winter by the cold and windy weather.

## Other jobs to do now

In spring, tie in the new, flexible stems of climbers. When pruning, you will have removed a lot of the old twining growths that helped the plants hold on to their supports, so they will now need extra help until the new stems have become more established.

Climbing and rambling roses, in particular, don't have a natural twining habit, so they definitely need to be tied in. Likewise, clematis has lots of soft growth that is easily damaged by the wind if it is not secured.

Use garden twine to tie plants to their supports. If you are tying in large climbers with thicker stems, such as roses, you could use sturdy, flexible tube ties.

# Pruning calendar: summer

## Trees to prune

Summer is a good time to prune all trees, especially the stone fruits, such as cherries, flowering cherries, and plums (*Prunus*), and members of the rowan (*Sorbus*) family. These trees are prone to bacterial cankers, and pruning now helps to avoid these diseases. In late summer, prune espalier apple and pear trees.

## Shrubs to prune

In early summer, prune *Garrya*. Shorten leggy growths on late-flowering *Camellias* after flowering has finished; if they have outgrown their situation, they can be hard-pruned now. Prune spring- and early summer-flowering shrubs like *Deutzia*, *Philadelphus*, shrubby *Lonicera*, *Kolkwitzia*, and *Weigela* so they grow plenty of new stems for next year's flowers. In late summer, prune *Escallonia*.

## Climbers to prune

In early summer, trim *Clematis macropetala* and *C. alpina,* and trim overgrown *C. montana*. Prune leggy growth of wisterias to help flower bud production, and ivy (*Hedera*) if you didn't prune it in spring. After flowering, cut back climbing honeysuckles (*Lonicera*) and the old flowerheads of climbing hydrangeas (*Hydrangea petiolaris*).

## Hedge care

Prune all types in late summer once nests are abandoned; berrying hedges can be left until spring to provide food for wildlife. Prune formal hedges at least twice in summer. Trim lavender (*Lavandula*) hedges lightly after flowering.

Prune all stone fruits, such as *Prunus serrula*.

You can prune ivy from spring to fall to keep it neat.

## Main pruning tasks

Summer is the time to enjoy the results of your winter and spring pruning, but there are still important pruning jobs to do to keep your garden looking its best.

Formal hedges need to be trimmed several times during the summer to keep their clean, sharp edges. Topiary should also be trimmed a few times to maintain its shape. Do not prune boundary hedges until late summer.

Deadhead roses to encourage repeat flowering, and prune late spring- and early summer-flowering shrubs immediately after they have bloomed, since next year's flowers will be on stems made this year. Also prune back any shrubs, trees, or climbers that are putting on too much growth or causing an obstruction.

## Other jobs to do now

Continue to train and tie in climbers during the summer. Climbing and rambling roses must be tied in regularly to protect long growths from wind damage, since they hold next year's flowering display. Also tie in Group 3 clematis to hold plants together, and wisteria to fill any gaps in coverage and to protect stems from wind damage.

Remove any diseased or dead growth on trees at any time. Dispose of diseased material by burning responsibly or taking it to a waste disposal site—don't compost it.

Trees can look quite different when clothed with leaves,so compare them in summer and winter before deciding what to prune. Leaves weigh down branches and can block paths or views, so some stems may need to be removed.

# Pruning calendar: fall

## Trees to prune

Fall is not a good time to prune trees as fungal spores can land on pruning cuts, increasing the risk of infection.

## Shrubs to prune

Although most pruning jobs are best left until late winter or early spring, you should reduce the height of hybrid tea and floribunda roses by one-third to prevent their stems from rocking in winter winds and damaging the main stem and roots. Also remove *Buddleja* flowerheads and the top one-third of the shoots to stop the plant from self-seeding. Do not remove spent hydrangea flowerheads as they help to protect developing flower shoots from frost, and also provide attractive architectural structure in winter. Seedheads, fruits, and berries that are left on shrubs now have both wildlife and decorative value.

## Climbers to prune

Fall is the ideal time to prune climbing and rambling roses. These plants still have sap in their stems, which makes them pliable and easy to train onto their supports. If the job is left until winter, the stems lose their flexibility and are more likely to snap. You can also prune Virginia creeper and Boston ivy (*Parthenocissus*) after leaf fall.

## Hedge care

Any hedges not pruned in summer can be cut back now, but do not prune wildlife hedges, which are best left until spring, as their fruit and berries provide food for birds and other wildlife through the colder months.

Trees are prone to infections in fall, so do not prune them.

Prune the climber *Parthenocissus* after leaf drop.

## Main pruning tasks

Don't prune trees and shrubs in the fall unless it is absolutely necessary. There are many fungal spores around at this time of the year and a high risk of diseases penetrating the cut surfaces.

It is, however, a good time to prune and train climbing and rambling roses as their stems are quite flexible and easily trained now. Reduce the height of hybrid tea and floribunda roses by one-third to prevent wind rock. Catch up with any pruning that you missed or didn't have time for in the summer, such as pruning back leggy growths on wisterias. It is also an ideal time to clean and sharpen pruning tools. Then sit back and admire the foliage and fruiting displays around you.

## Other jobs to do now

Fall is tidying-up time. Cover trees or shrubs that need frost protection, such as palms, tree ferns, and fruits like apricots. Leave the fronds on tree ferns and palms, as they protect plants from frost. For further protection, tie them together over the crown.

As the leaves fall, the basic structure of plants becomes more visible, and you will be able to see more clearly what needs to be pruned in spring. Rake up fallen leaves and fruit, such as apples, and use to make compost and leafmold, which you can later spread under pruned plants to feed and mulch them.

If you have any logs left from pruning in the summer, you could construct a log pile, which benefits wildlife.

# Pruning calendar: winter

## Trees to prune

This is a good time to prune a wide range of trees and shrubs (with the exception of stone fruits) as you can clearly identify crossing branches and diseased wood. Prune trees with ornamental bark, such as *Acer davidii* and *Acer griseum* and birches. Apple and pear trees should also be pruned in winter.

## Shrubs to prune

Prune any large or overgrown shrubs, such as *Mahonia* or *Philadelphus*, which can be cut back hard now or in early spring. You may lose the coming year's flowers by hard-pruning, but the plant will recover the following year.

## Climbers to prune

Spur-prune wisteria in the winter, as the buds are not swelling and are less likely to be damaged. Also tackle *Actinidia* and Virginia creeper (*Parthenocissus*), and renovate overgrown ivies (*Hedera*). Remove long growths from around doors and window frames, and also where they have invaded gutters and grown under roof shingles. Shorten the main stems of all overly tall climbers, such as *Hydrangea petiolaris*.

## Hedge care

Winter is the time for renovation work, reducing the height and width of overgrown hedges. Brush off snow from flat-topped hedges as its weight can damage their structure. Leave the crisp, bronzed foliage on hornbeam and beech hedges in the winter months because it adds ornamental value and also makes an excellent windbreak.

Prune apple trees in winter when their structure is more visible.

Brush snow off the top of hedges to prevent structural damage.

## Main pruning tasks

Late winter or early spring is a good time to hard-prune overgrown shrubs, which are dormant at this time of the year. You can also see clearly the structure and naked silhouettes of trees, making them easier to prune. Summer is the ideal time to prune many trees, but winter is sometimes better because you may have more time to do the job properly. However, do not prune cherries and plums (*Prunus*), or members of the rowan (*Sorbus*) family.

You can also now admire the results of your earlier pruning efforts, with the attractive trunks and stems of trees and shrubs like the snakebark maple (*Acer davidii*), birch (*Betula*), cherry (*Prunus serrula*), and dogwood (*Cornus*) creating stunning winter features.

## Other jobs to do now

Tie in anything that needs to be supported. At the same time, check that ties and supports have not been damaged during storms, or become too tight around stems and trunks. Bring berries and evergreen branches into the house for festive winter decorations.

You can dispose of pruning material (and old Christmas trees) in a variety of ways. Shred the woody waste to make a valuable mulching material, and compost soft growth. Burning material is an alternative method, but check your local regulations before you burn, and be considerate of neighbors. Alternatively, take all your off-cuts to your local waste disposal site, along with any diseased material, if you do not plan to burn it.

# Root vegetables: potatoes

**Potato '*Red Duke of York*'**
A vigorous first early, producing abundant, good-sized, red-skinned tubers with delicious pale yellow flesh. Perfect in salads when small, and boiled or baked when larger. Young shoots need protection from frost.

**Plant:** early spring
**Harvest:** early to midsummer
💧◑☼

**Potato '*Foremost*'**
Harvest this useful early variety from early summer or lift as required throughout the summer. The white-skinned, white-fleshed crop has a firm texture, ideal for salads and boiling. Protect young shoots from frost.

**Plant:** early spring
**Harvest:** early to late summer
💧◑☼

**Potato '*Arran Pilot*'**
A popular first early, excellent for gardeners eager to enjoy large yields of small potatoes with creamy, waxy flesh. Good scab resistance and tolerance of dry spells. Young shoots need protection from frost.

**Plant:** early spring
**Harvest:** early to midsummer
💧◑☼

**Potato '*Mimi*'**
The ideal first early for containers, producing masses of small red tubers with incredibly tasty, waxy, cream-colored flesh. An excellent salad potato with good scab resistance. Protect new shoots from frost.

**Plant:** early spring
**Harvest:** early summer
💧◑☼

**Potato '*Charlotte*'**
A supermarket favorite because of its long, smooth, yellow tubers, with fabulously flavored, waxy flesh. This second early is easy to grow in the garden, and one of the best salad potatoes.

**Plant:** mid-spring
**Harvest:** mid- to late summer
💧◑☼

**Potato '*Saxon*'**
For baking, boiling, and french-frying, try this floury-textured second early. The large, white tubers have a mild, creamy flavor, and the plants display a useful resistance to both blackleg and eelworm.

**Plant:** mid-spring
**Harvest:** mid- to late summer
💧◑☼

**Potato '*Royal Kidney*'**
An old maincrop salad variety, 'Royal Kidney' produces delicious, yellow-fleshed salad potatoes from late summer. It is also tempting to dig up the plants earlier for crops of tender baby potatoes.

**Plant:** mid-spring
**Harvest:** late summer

**Potato '*Ratte*'**
The long, slightly knobby tubers harvested from this maincrop variety are a real treat. Their dense, waxy, yellow flesh has a strong nutty flavor, making them perfect for salads.

**Plant:** mid-spring
**Harvest:** late summer

**Potato '*Pink Fir Apple*'**
A curious old maincrop variety, producing long, irregular tubers with pink-tinged skin that is best left on during cooking. The waxy flesh, with its earthy flavor, is popular in salads, and the tubers store well.

**Plant:** mid-spring
**Harvest:** from early fall

**Potato '*Kerrs Pink*'**
This versatile and high-yielding maincrop variety is reliable in most soils. The blush pink tubers have delicious floury cream flesh that is perfect for mashing, french-frying, roasting, and baking. Stores well.

**Plant:** mid-spring
**Harvest:** from early fall

**Potato '*Sante*'**
An excellent choice for organic gardeners because of its excellent pest and disease resistance, this maincrop variety yields large cream tubers that are great for baking, boiling, and roasting. Stores well.

**Plant:** mid-spring
**Harvest:** from late summer

**Potato '*Nicola*'**
Resistance to eelworm and blight makes this variety a good option for maincrop salad potatoes. Large crops of long, yellow, waxy tubers are reliably produced and store well over winter.

**Plant:** mid-spring
**Harvest:** from late summer

# Root vegetables: carrots, beets, parsnips

**Carrot *'Parmex'***
Dumpy, spherical roots make this one of the best carrots for sowing into patio pots or shallow soil. Despite their shape, they have a fine sweet flavor. The earliest crops can be sown under glass or protected with cloches.

**Sow:** early to late spring
**Harvest:** late spring to early fall

**Carrot *'Infinity'* F1**
This late maincrop carrot has an elegant, slender root that is delicious raw or cooked. The sweet carrots are deep orange right to their core and keep well in the soil into fall or can be lifted and stored successfully.

**Sow:** early spring to midsummer
**Harvest:** late summer to late fall

**Carrot '*Flyaway*' F1**
Specially bred to be less prone to attack by carrot flies, this maincrop carrot produces good crops where the pest would render others inedible. The thick, cylindrical roots are smooth-skinned and sugary.

**Sow:** early spring to midsummer
**Harvest:** late spring to mid-fall

**Carrot '*Purple Haze*' F1**
As its name suggests, this variety has unconventional dark purple roots, which reveal contrasting orange cores when they are sliced. Flavor is not sacrificed and is particularly good when raw.

**Sow:** early spring to early summer
**Harvest:** early summer to late fall

**Carrot '*Bangor*' F1**
Long, stocky roots are produced in large quantities, especially in moist soil, by this excellent maincrop variety. Crops can be harvested from late summer and throughout fall, and store well once lifted.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to late fall

**Carrot '*Carson*' F1**
Fall and winter bring good crops of this medium-sized, tapering variety. The rich orange color, combined with the delicious crunchy texture and sweetness, makes them irresistible when eaten raw.

**Sow:** mid-spring to midsummer
**Harvest:** late summer to early winter

**Beet '*Boltardy*'**
A reliable variety yielding traditional deep red globe-shaped roots with a fine sweet flavor. Perfect for sowing under cloches in early spring because of its excellent resistance to bolting.

**Sow:** early spring to midsummer
**Harvest:** early summer to mid-fall

**Beet '*Chioggia Pink*'**
A beautiful curiosity; the rich red skin of this spherical root conceals flesh marked with concentric rings of blush pink and white. Its sweet, mild flavor is delightful raw or cooked.

**Sow:** mid-spring to midsummer.
**Harvest:** early summer to mid-fall

**Beet '*Forono*'**
Elongated, burgundy-colored roots make this variety ideal for slicing. Tender young roots have a particularly intense flavor, so sow successionally for a continuous supply. Prone to bolting if sown too early.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to late fall

**Beet '*Pablo*' F1**
One of the best varieties for growing in patio containers and perfect to harvest as baby beets. The smooth, deep red, spherical roots taste exceptionally sweet; they also stand well in the soil without bolting or becoming woody.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**Parsnip '*Gladiator*' F1**
A popular hybrid parsnip that matures quickly, producing consistently reliable, early-maturing crops of white-skinned roots. 'Gladiator' also benefits from good canker resistance.

**Sow:** late winter to mid-spring
**Harvest:** mid-fall to early spring

**Parsnip '*Tender and True*'**
In deep soil, this variety forms exceptionally long roots, which are often considered to have one of the finest parsnip flavors. It is also resistant to canker and is a firm favorite with exhibition growers.

**Sow:** late winter to mid-spring
**Harvest:** late fall to early spring

# Root vegetables: turnips, rutabagas, radishes

**Turnip '*Snowball*'**
For a quick crop, this fast-maturing variety is one of the best. The pure white globes are best harvested while young, when their deliciously crisp, firm, white flesh can be enjoyed raw or cooked.

**Sow:** early spring to midsummer
**Harvest:** late spring onward

**Turnip '*Purple Top Milan*'**
A good choice for early sowings under cloches, this turnip crops reliably and matures quickly. The flat-topped roots are a vivid shade of purple above the soil and pure white beneath it, making them attractive as well as delicious.

**Sow:** early spring to midsummer
**Harvest:** mid-spring onward

**Rutabaga '*Brora*'**
This gem among rutabagas has the classic purple top and cream base, but has been bred to produce the finest smooth flesh without any bitterness. Best harvested in early winter to avoid woodiness.

**Sow:** late spring to midsummer
**Harvest:** mid-fall to midwinter

**Radish '*French Breakfast*'**
A torpedo-shaped variety with rosy red skin and a bright white tip. Its shape makes it great for slicing, and the crunchy flesh has a mild flavor with just a hint of peppery heat. Easy and quick to grow.

**Sow:** early spring to early summer
**Harvest:** late spring to mid-fall

**Radish '*Cherry Belle*'**
Probably one of the best vegetables for the absolute beginner, these small, round, brilliant red radishes tolerate poor-quality soil. They grow rapidly, are slow to become woody, and have tasty, mild-flavored flesh.

**Sow:** early spring to early summer
**Harvest:** late spring to mid-fall

**Chinese radish *'Mantanghong'* F1**
For a taste of the exotic, try these easy-to-grow, tennis-ball-sized radishes. Their plain, pale green skin hides vivid magenta flesh with a white outer layer, which has a nutty flavor and a touch of heat.

**Sow:** early summer to midsummer
**Harvest:** late summer to early winter

# Brassicas: cabbages

**Cabbage '*Pixie*'**
One of the earliest pointed cabbages, which can be picked young as spring greens or allowed to mature into a firm-hearted cabbage. A reliable crop that can be harvested in time to leave soil clear for spring sowings.

**Sow:** midsummer
**Harvest:** midwinter to late spring

**Cabbage '*Derby Day*'**
A traditional, pale green ballhead cabbage for early summer harvest. Its resistance to bolting has long made it popular with gardeners, and the mature cabbages can stand even summer heat.

**Sow:** late winter to early spring
**Harvest:** early to late summer

**Cabbage '*Hispi*' F1**
Another favorite, this pointed cabbage reliably produces compact, tasty, dark green heads. The cabbages mature rapidly, and successional sowings provide a harvest from late spring into fall.

**Sow:** late winter to late summer
**Harvest:** late spring to late fall

**Cabbage '*Marner Early Red*' (syn. '*Marner Fruerot*')**
This dense-hearted cabbage is one of the first reds to reach maturity. The outer leaves are tinged with gray; the head is an intense red and has a peppery flavor best appreciated raw.

**Sow:** midwinter to early spring
**Harvest:** midsummer to late summer

**Cabbage '*Minicole*' F1**
Ideal for small gardens, this white ballhead cabbage produces small, uniform heads on compact plants. Plant closely for a bumper harvest of fall cabbages, which will stand in the ground for up to three months.

**Sow:** early to late spring
**Harvest:** early fall to early winter

**Cabbage '*Red Jewel*' F1**
The claret-colored leaves dusted with silver make this one of the best cabbages for ornamental plantings. The tight round heads also taste delicious and will stand in the ground well or store indoors.

**Sow:** early spring to early summer
**Harvest:** midsummer to early fall

# Brassicas: cabbages, calabrese, broccoli, cauliflower

**Cabbage '*January King 3*'**
This traditional winter cabbage has good frost resistance and appetizing, sweet, crunchy leaves. The frilly-edged leaves are tinged with pink and also look beautiful in the winter garden.

**Sow:** mid-spring to early summer
**Harvest:** late fall to late winter

**Cabbage '*Tundra*' F1**
A cross between a savoy and a white cabbage, this extremely hardy variety produces solid round heads of tasty crisp leaves. The long cropping season makes this a really useful addition to the vegetable patch.

**Sow:** early spring to early summer
**Harvest:** mid-fall to early spring

**Cabbage '*Savoy Siberia*' F1**
A truly tough vegetable, this savoy withstands hard winters, so is ideal for exposed or cold gardens. The blue-green, blistered leaves taste sweet, and the cabbages stand well in the ground for long periods.

**Sow:** early spring to early summer
**Harvest:** early fall to midwinter

**Calabrese '*Corvet*' F1**
A reliable variety of fall vegetable, producing robust plants and a bumper crop of dense, green heads. Cut the central head while its flowers are still tightly closed for a second harvest of smaller shoots a few weeks later.

**Sow:** mid- to late spring
**Harvest:** late summer to early fall

**Broccoli '*Bordeaux*'**
This purple sprouting variety is very useful for those who can't wait until spring for broccoli. It is not winter-hardy and does not require the usual exposure to cold to produce its tasty spears.

**Sow:** late winter to mid-spring
**Harvest:** midsummer to mid-fall

**Broccoli '*White Star*'**
Creamy white rather than purple flowers make the spears of this spring variety reminiscent of cauliflower; many consider the taste similar, too. Reliably high yields produced over a long period make it a popular choice.

**Sow:** mid- to late spring
**Harvest:** early to mid-spring

**Broccoli '*Claret*' F1**
A large, vigorous plant that may need staking in windy gardens, this variety produces huge yields of chunky, succulent spears in spring. The purple flowerheads are tightly packed and uniform, and taste delicious.

**Sow:** mid- to late spring
**Harvest:** early to mid-spring
💧 ☼

**Broccoli '*Late Purple Sprouting*'**
To extend your broccoli crop into late spring, try this slightly later-flowering variety. It is slow to go to seed, and the delicious purple-budded spears can be cut over a long period.

**Sow:** mid- to late spring
**Harvest:** early to late spring
💧 ☼

**Cauliflower '*Walcheran Winter Armado April*'**
An extremely hardy winter variety that tolerates heavy frost and produces large, solid, pure white heads. It ties up a bed for 12 months, so it may not be suitable for very small gardens.

**Sow:** mid- to late spring
**Harvest:** early to late spring
💧 ◑ ☼

**Cauliflower '*Mayflower*' F1**
High-quality, dense white curds are consistently produced by this vigorous early summer variety. Unlike many others, it does not require high nitrogen levels and is harvested early enough to avoid midsummer droughts.

**Sow:** mid- to late winter and mid-fall **Harvest:** late spring to midsummer 💧 ◑ ☼

**Cauliflower '*Romanesco*'**
If you want something different, try this strange summer/fall variety, with pyramid-shaped heads in a vibrant shade of acid green. Grow over a long season for large heads or sow successionally for frequent small crops.

**Sow:** early to late spring
**Harvest:** late summer to early winter
💧 ◑ ☼

**Cauliflower '*Violet Queen*' F1**
The vivid purple curds formed by this variety will brighten up any vegetable patch, although they turn green when cooked. Plenty of nitrogen and water are required to sustain strong growth.

**Sow:** late spring to early summer
**Harvest:** late summer to early fall
💧 ◑ ☼

# Brassicas: Brussels sprouts, kale, kohlrabi, oriental greens

**Brussels sprouts '*Red Delicious*'**
This magnificent variety is a striking shade of red-tinged-purple from its crowning leaves to the base of its stem. Unlike many other red varieties, the sprouts retain their color after cooking and have a fine flavor.

**Sow:** early to mid-spring
**Harvest:** early winter

**Brussels sprouts '*Trafalgar*' F1**
If your aim is sweet sprouts for Christmas, then this variety will not disappoint. Dense crops of firm, uniformly-sized sprouts grow on tall, sturdy plants and can be harvested throughout the winter.

**Sow:** early to mid-spring
**Harvest:** late fall to midwinter

**Brussels sprouts '*Bosworth*' F1**
Dark green, dense, sweet sprouts are produced in abundance by this tough hybrid variety, which will stand well through cold winter weather. Some tolerance to downy mildew helps ensure a healthy crop.

**Sow:** early to mid-spring
**Harvest:** late fall to early winter

**Kale '*Redbor*' F1**
All kales are useful hardy winter crops, but the tall leaves of this variety resemble large clumps of burgundy, curly-leaved parsley and add some welcome color to dull days. Great steamed or stir-fried.

**Sow:** early to late spring
**Harvest:** early fall to early spring

**Kale '*Starbor*' F1**
More compact than most kales, this variety is well suited to the small or windswept garden. The tightly curled green leaves stand up well to winter cold. Try successional sowings for a year-round crop of tasty baby leaves.

**Sow:** early spring to early summer
**Harvest:** early fall to early spring

**Kale '*Nero di Toscana*'**
Also known as Black Tuscany or Cavolo Nero, this is the favored kale in Italian kitchens. Its upright leaves are almost black and blistered like those of savoy cabbages. Use mature leaves in soups and stews, baby ones in salads.

**Sow:** early spring to early summer
**Harvest:** early fall to early spring

**Kohlrabi '*Olivia*' F1**
Harvest the swollen stem that sits just above soil level when it is about the size of a tennis ball, and enjoy the crisp, white flesh grated raw in salads or lightly steamed. Reliable, with little woodiness, this variety is slow to bolt.

**Sow:** early spring to early summer
**Harvest:** late spring to mid-fall

**Kohlrabi '*Purple Danube*' F1**
The vibrant purple skin and stems of this variety are striking in the garden, and its sweet nutty flavor is one of the best. Purple varieties take longer to mature than white, so this makes a good late summer and fall crop.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to late fall

**Bok choy '*Joi Choi*'**
Summer stir-fries will be fresher and tastier with the addition of these succulent, crispy, home-grown leaves. This variety has attractive bright white stems that carry deep green, rounded leaves, and it is easy to grow.

**Sow:** mid-spring to early fall
**Harvest:** early summer to mid-fall

**Mizuna**
Often found in supermarket salad mixes, these jagged-edged, slightly mustard-flavored leaves are simple to cultivate over summer. Harvest baby leaves for salads or allow plants to mature and use leaves for stir-frying.

**Sow:** early spring to early fall
**Harvest:** late spring to late fall

**Mibuna**
Similar in flavor to mizuna, but with a stronger peppery tang and long, smooth-edged foliage. Like mizuna, this is an ideal cut-and-come-again crop that can be sown successionally from spring to fall.

**Sow:** early spring to early fall
**Harvest:** late spring to late fall

**Mustard '*Red Giant*'**
Another beautiful, strongly flavored leaf, this ruby-tinged mustard is best harvested while the leaves are small, otherwise the peppery flavor can be overpowering. Hardy enough to stand over winter from a fall sowing.

**Sow:** early spring to early fall
**Harvest:** late spring to midwinter

# Salad and leafy vegetables: lettuce, spinach, arugula

**Lettuce '*Sangria*'**
This butterhead type matures to form a loose heart with soft leaves, and a pretty red flush that will brighten up a salad. Easy to grow and quick to mature, it does well in poorer soil and has some resistance to mildew.

**Sow:** early spring to late summer
**Harvest:** late spring to mid-fall

**Lettuce '*Tom Thumb*'**
A gardeners' favorite, this compact, green butterhead lettuce rapidly forms dense, sweet-tasting hearts. Ideal for small gardens because it can be planted at high densities and is ready for harvest quickly.

**Sow:** early spring to midsummer
**Harvest:** late spring to early fall

**Lettuce '*Little Gem*'**
This cos lettuce is familiar from the supermarket shelves, but is even crisper and sweeter if you grow it yourself. Its diminutive size makes it perfect for small gardens, and it is one of the fastest-cropping cos types.

**Sow:** early spring to midsummer
**Harvest:** late spring to early fall

**Lettuce '*Freckles*'**
This semi-cos variety forms an open head with green leaves that are spectacularly splattered with red. A good choice for flower borders, where it matures quickly. Plants are slow to bolt, even in warm weather.

**Sow:** early spring to late summer
**Harvest:** late spring to mid-fall

**Lettuce '*Delicato*'**
Loose leaf lettuces are the quickest and easiest to grow, either as cut-and-come-again baby leaves or for harvesting whole when mature. This deep red oakleaf variety has a pleasant flavor.

**Sow:** early spring to midsummer
**Harvest:** mid-spring to mid-fall

**Lettuce '*Catalogna*'**
A tasty, green oakleaf lettuce that you will not want to forget to sow successionally all through summer. The tender leaves have a fine flavor and the non-hearting plants are slow to bolt, should they get the chance.

**Sow:** early spring to midsummer
**Harvest:** mid-spring to mid-fall

**Lettuce '*Lollo Rossa-Nika*'**
The red leaves of this frilled lettuce are so dark as to be almost purple and are incredibly ornamental as well as appetizing. Young leaves taste sweet, and, although they turn bitter as they grow, the curled heads look fabulous.

**Sow:** early spring to midsummer
**Harvest:** late spring to mid-fall

**Lettuce '*Challenge*'**
Crisphead lettuces are similar to the iceberg types. This reliable variety forms large, solid hearts of crunchy leaves and performs well when sown early and late under cloches. Good resistance to mildew and bolting.

**Sow:** early spring to midsummer
**Harvest:** late spring to mid-fall

**Lettuce '*Sioux*'**
A pretty red-tinged iceberg variety, with leaves that intensify in color in warmer weather, giving the plants good ornamental qualities that are so valuable in small gardens. Perfect color and crunch for salads.

**Sow:** early spring to midsummer
**Harvest:** early summer to mid-fall

**Spinach '*Perpetual Spinach*'**
Not a true spinach, but spinach beet, with a taste similar to Swiss chard. It is easy to grow because it rarely runs to seed, even in dry conditions. Succulent green leaves are produced prolifically and crops can be gathered all winter.

**Sow:** mid-spring to midsummer
**Harvest:** any time

**Spinach '*Tetona*' F1**
A high-yielding spinach producing a profusion of rounded dark green leaves. This is the perfect variety for sowing as a cut-and-come-again crop to produce baby leaves for salads, but it can also be left to mature.

**Sow:** early spring to late summer
**Harvest:** late spring to late fall

**Arugula '*Apollo*'**
This cultivated variety has large, rounded, green leaves and a strong peppery flavor without any bitterness. The plant is easy to grow as a cut-and-come-again crop in pots or in the ground. Water well in hot weather.

**Sow:** early spring to midsummer
**Harvest:** mid-spring to mid-fall

# Leafy vegetables: arugula, chicory, Swiss chard

**Arugula '*Rocket Wild*'**
A popular salad leaf with slim, divided leaves and a pungent peppery taste. Easy to grow in pots or beds, it does not bolt as quickly as cultivated forms, but pick the leaves frequently for a longer cropping period.

**Sow:** early spring to early fall
**Harvest:** from mid-spring (through winter under cover) ◑ ◊ ☼ ☀

**Chicory '*Italiko Rosso*'**
Red-stemmed asparagus, or catalogna chicory, grows well in poor soil and is ideal for harvesting as baby leaves to add a slightly bitter tang to salads. Alternatively, allow the foliage to mature and eat lightly steamed.

**Sow:** late spring to early fall
**Harvest:** midsummer to late fall
◊ ☼ ☀

**Chicory '*Sugar Loaf*'**
Treat in the same way as lettuce to produce tall, pale heads of crisp, bitter leaves or cut-and-come-again baby leaves. Chicory grows well in poorer soil, although watering may be required in dry spells.

**Sow:** mid-spring to late summer
**Harvest:** midsummer to mid-fall
◊ ☼ ☀

**Swiss chard '*Bright Lights*'**
Multicolored stems ranging from white and yellow to pink and purple make this a vibrant addition to the vegetable garden and flower border. Easy to grow, it reemerges in early spring if given winter protection.

**Sow:** mid-spring to midsummer
**Harvest:** early spring to mid-fall
◑ ◊ ☼

**Swiss chard '*Charlotte*'**
One of the most attractive ruby chards, with bright red stems and contrasting green leaves veined a striking red. It looks fabulous in a pot or flower border, and the baby leaves liven up salads. A must for every garden.

**Sow:** mid-spring to midsummer
**Harvest:** at any time
◑ ◊ ☼

**Swiss chard '*Lucullus*'**
Decorative and delicious, this chard rapidly produces generous crops of large green leaves on sturdy, pure white stems. Leaves and stems may be boiled, steamed, or stir-fried; their mild flavor is similar to beets.

**Sow:** mid-spring to midsummer
**Harvest:** early spring to mid-fall
◑ ◊ ☼

# Cucurbits: zucchini, summer squash

**Zucchini '*Zucchini*'**
A reliable variety that forms a bushy plant, well suited to growing in a container. Zucchini with dark green skins and tasty pale flesh are produced in profusion from midsummer. Like all zucchini, they are best picked young.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to early fall
◊ ◑ ☼

**Zucchini '*Defender*' F1**
A phenomenally productive early variety. If harvested small, fruits will keep coming until mid-fall, and they are delicious. Plants are resistant to cucumber mosaic virus, which can cause other varieties to fail.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall
◊ ◑ ☼

**Zucchini '*Burpee's Golden*'**
Another prolific zucchini variety that bears numerous decorative and delicious bright yellow fruits. The zucchini have a particularly fine flavor, especially when harvested small.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to early fall
◑ ◊ ☼

**Zucchini '*Tromboncino*'**
This vigorous Italian variety is best trained up a sunny wall to afford everyone a good view of its long, curved, bulbous-ended fruits. The pale green fruits can reach more than 12 in (30 cm) long.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to early fall
◑ ◊ ☼

**Zucchini '*Venus*' F1**
Unusually compact, these plants are great for containers or small gardens, and still produce ample crops of delicious, mid-green zucchini. In good conditions, fruits are ready to harvest 60 days after planting.

**Sow:** mid-spring to early summer
**Harvest:** early summer to mid-fall ◑ ◊ ☼

**Summer squash '*Long Green Bush*'**
Despite its name, this variety forms quite a compact, bushy plant, making it suitable for the smaller garden. Long, deep green fruits, with pale green marrow stripes, swell rapidly, but can be picked as zucchini when small.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall
◑ ◊ ☼

# Cucurbits: squash, cucumbers

**Squash '*Sunburst*' F1**
A yellow "patty pan" variety, this squash has vibrant butter-colored fruits, shaped like flying saucers. Large crops of flavorsome fruits are produced by this easily grown variety if regular harvesting is carried out.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**Squash '*Uchiki Kuri*'**
Also known as 'Red Kuri', this squash produces several medium-sized, bright orange fruits, with delicious, nutty, golden flesh. It performs particularly well in temperate climates. Fruits store well once cured.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall

**Squash '*Pilgrim Butternut*' F1**
A less vigorous and so more manageable butternut squash for the smaller garden. The semi-bush habit of the vine does not prevent a good crop of beige-skinned, orange-fleshed squashes, which store well.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall

**Squash '*Crown Prince*' F1**
This trailing squash is a favorite because of its exceptionally good nutty-flavored flesh. The steely gray skin of the fruits contrasts dramatically with the orange flesh and looks attractive on the vine.

**Sow:** mid-spring to late spring
**Harvest:** late summer to mid-fall

**Squash '*Turk's Turban*'**
Not an exceptional culinary squash, with pale yellow flesh and a turnip-like flavor, but often grown for its ornamental qualities. The rich orange skin folds and forms a bulge splashed with green and cream.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall

**Squash '*Festival*' F1**
Ornamental and delicious, this trailing vine produces high yields of small, squat, orange-and-cream-striped squashes, with sweet, nutty-tasting, cream flesh. The squashes are perfect for stuffing or baking, and store well.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall

**Cucumber '*Bush Champion*' F1**
Grow this ridge cucumber outdoors—its compact plants are ideal for small gardens and pots, and have good tolerance to cucumber mosaic virus. The slightly knobby, dark green, sweet fruits reach about 4 in (10 cm) long.

**Sow:** mid-spring to early summer
**Harvest:** late summer to mid-fall
☼ ◑ ☼

**Cucumber '*Marketmore*'**
An excellent, high-yielding cucumber, producing sturdy, deep green fruit up to 8 in (20 cm) long, with no bitterness. This variety does well outdoors on a teepee or trellis. Resistance to cucumber mosaic virus is a bonus.

**Sow:** mid-spring to early summer
**Harvest:** late summer to mid-fall
☼ ◑ ☼

**Cucumber '*Masterpiece*'**
Crisp, juicy, white flesh, under a deep green, slightly spiny skin, makes this ridge cucumber a good choice for outdoor cultivation. This variety crops reliably, but performs best when allowed to climb.

**Sow:** mid-spring to early summer
**Harvest:** late summer to mid-fall
☼ ◑ ☼

**Cucumber '*Zeina*' F1**
An all-female variety that can be grown in the greenhouse or outdoors. Small, succulent, smooth-skinned cucumbers can be harvested over a long season and are a handy size to eat at one meal.

**Sow:** early spring to early summer
**Harvest:** midsummer to mid-fall
☼ ◑ ☼

**Cucumber '*Petita*' F1**
For an abundance of juicy, miniature cucumbers from the greenhouse, this is the variety to choose. It is easy to grow, even in difficult conditions, and has all female flowers so bitter fruits are not produced.

**Sow:** early spring to early summer
**Harvest:** midsummer to mid-fall
☼ ◑ ☼

**Cucumber '*Carmen*' F1**
Resistance to powdery mildew, scab, and leaf spot makes this all-female variety a good choice for greenhouse cultivation. Impressive harvests of straight, smooth, green fruits are simple to produce.

**Sow:** early spring to early summer
**Harvest:** midsummer to mid-fall
☼ ◑ ☼

# Allium family: onions, shallots, green onions

**Onion '*Ailsa Craig*'**
An old favorite, this reliable variety yields heavy crops of large, sweet onions, with smooth yellow-brown skin. Best sown as seed in spring to produce a good fall crop that stores well if allowed to dry.

**Sow:** late winter to early spring
**Harvest:** late summer to early fall
💧 ☼

**Onion '*Sturon*'**
Traditionally grown from sets, this variety produces large, round, yellow-brown bulbs that have a strong skin, which makes them an excellent choice for winter storage. Seed is occasionally available.

**Plant sets:** late winter to early spring
**Harvest:** late summer to early fall
💧 ☼

**Onion '*Red Baron*'**
Widely available as both seeds and sets, this variety has a rich red skin, with pronounced pink stripes between the bulb's layers. It will store for only a limited time.

**Sow:** late winter to mid-spring
**Plant sets:** early spring
**Harvest:** early to mid-fall
💧 ☼

**Onion '*Senshyu*'**
Sets of this useful winter Japanese variety should be planted in fall and seeds sown a little before for an early summer harvest. The semi-flat, straw-colored bulbs grow to a good size and have a strong flavor.

**Sow:** late summer
**Plant sets:** early to mid-fall.
**Harvest:** early to midsummer 💧 ☼

**Onion '*Shakespeare*'**
For an early summer crop of globe-shaped onions with rich brown skins, try this British overwintering variety. The dense white flesh and sturdy skin mean that they store well, and they have an excellent flavor.

**Sow:** early to mid-fall
**Harvest:** early to midsummer
💧 ☼

**Shallot '*Longor*'**
An attractive, elongated variety of shallot, with a pink flush to the skin and inner layers. The strongly flavored bulbs store well through fall and winter if carefully dried. Quicker to crop than traditional bulb onions.

**Plant sets:** late winter to mid-spring
**Harvest:** mid- to late summer
💧 ☼

**Shallot '*Red Sun*'**
One of the most reliable red shallots, this variety has wonderful burgundy skin and white flesh with layers divided by pink rings. Appetizing chopped raw in salads, it is also well suited to cooking and pickling.

**Plant sets:** early to mid-spring
**Harvest:** mid- to late summer
💧☼

**Shallot '*Golden Gourmet*'**
Large and yellow-skinned, this high-yielding variety produces bumper crops of good-quality bulbs from sets and is easy to store all through the winter. It is less prone to bolting in dry conditions than many shallots.

**Plant sets:** late winter to mid-spring
**Harvest:** mid- to late summer
💧☼

**Green onion '*Paris Silverskin*'**
A dual-purpose small white onion that can be harvested young as a salad onion or left in the ground to bulb up for pickling. Easy to grow and compact, it makes an ideal crop for small gardens.

**Sow:** early to mid-spring
**Harvest:** mid- to late summer
💧☼

**Green onion '*Guardsman*'**
This trusted, white-stemmed variety is extremely easy to grow. It is a good choice to sow successionally from spring to fall because it is hardy enough to overwinter and give an early spring crop. Resistant to white rot.

**Sow:** early spring to mid-fall
**Harvest:** late spring to mid-fall; late winter to early spring 💧☼

**Green onion '*North Holland Blood Red*'**
An attractive variety with bold red bases and a mild flavor. Use thinnings from early sowings as green onions, leaving wider-spaced plants to develop into red-skinned maincrop onions.

**Sow:** early spring to early summer
**Harvest:** late spring to late summer
💧☼

**Green onion '*White Lisbon*'**
A trusted old favorite, this variety produces white bulbs and bright green tops with a good, strong flavor. It is easy to grow but prone to downy mildew, so keep rows well spaced to avoid the spread of disease.

**Sow:** early spring to midsummer
**Harvest:** late spring to early fall
💧☼

# Allium family: leeks, garlic

**Leek '*Musselburgh*'**
An extremely hardy, sturdy leek, with a broad white stem topped by impressive green leaves, known as flags. This old variety can withstand the coldest winter, and can be harvested from late fall until late winter.

**Sow:** early to mid-spring
**Harvest:** late fall to late winter
💧 ☼

**Leek '*Hannibal*'**
This handsome leek has deep green leaves and a long, white, straight stem. Suitable for fall and early winter cropping, it also produces impressive mini leeks when planted close together.

**Sow:** early to mid-spring
**Harvest:** early fall to early winter
💧 ☼

**Leek '*Swiss Giant, Zermatt*'**
An elegant variety with a long, slender stem, which despite its name forms excellent mini leeks when planted at high densities. It is ready for harvest by late summer—an advantage for those with limited space in the garden.

**Sow:** early to mid-spring
**Harvest:** midsummer to late fall
💧 ☼

**Garlic '*Solent Light*'**
One of the best garlics for cool climates, this is best planted in fall but also does well planted in spring. It matures in late summer and because it is a nonflowering, softneck type, stores extremely well.

**Plant cloves:** mid-fall to early spring
**Harvest:** midsummer to early fall 💧 ☼

**Garlic '*Early Light*'**
This flowering, hardneck, purple-skinned variety is best used fresh but will store for about three months. The harvest will be eagerly anticipated, as this is one of the earliest varieties to crop in cool climates.

**Plant cloves:** mid-fall to midwinter
**Harvest:** late spring to early summer
💧 ☼

**Garlic '*Elephant Garlic*'**
Closely related to the leek, this giant produces bulbs up to 4 in (10 cm) in diameter. Use the large, juicy cloves fresh from the soil to enjoy their mild, sweet flavor, which makes them particularly suitable for roasting.

**Plant cloves:** mid-fall to midwinter.
**Harvest:** midsummer to early fall
💧 ☼

# Legumes: peas

**Pea '*Feltham First*'**
Early and dwarf, this is a useful, high-yielding pea variety for small gardens. Better results are often achieved from fall sowings in containers, where plants are given some protection.

**Sow:** mid- to late fall; midwinter to early spring
**Harvest:** late spring to midsummer
◑ ◊ ☼

**Pea '*Twinkle*'**
An excellent early variety, the first sowings of which perform best if protected under cloches when young. Dwarf plants give good crops of full pods and have resistance to pea wilt and tolerance to downy mildew.

**Sow:** late winter to mid-spring
**Harvest:** late spring to midsummer
◑ ◊ ☼

**Pea '*Hurst Greenshaft*'**
Pairs of long pods develop high on these plants, making harvesting of this traditional variety's consistently large crops somewhat easier. The peas are large and sweet, and plants have good disease resistance.

**Sow:** early spring to early summer
**Harvest:** late spring to early fall
◑ ◊ ☼

**Pea '*Rondo*'**
One of the tastiest and heaviest cropping peas, this double-podded variety has dark green, straight pods up to 4 in (10 cm) long. Plants need supports, but the succulent peas should be ample reward.

**Sow:** early spring to early summer
**Harvest:** late spring to early fall
◑ ◊ ☼

**Pea '*Sugar Snap*'**
A versatile sugar snap variety that can be picked young and eaten whole, raw, or stir-fried, or harvested when mature and podded for fresh peas. Plants grow up to 6 ft (1.8 m) tall, and need support from trellis or canes.

**Sow:** early spring to early summer
**Harvest:** late spring to late summer
◑ ◊ ☼

**Pea '*Oregon Sugar Pod*'**
An excellent snow pea variety that produces wide, flat pods best eaten whole, either raw, steamed, or stir-fried. Expect large yields of these crisp, sweet pods from plants that grow to 36 in (90 cm).

**Sow:** early spring to early summer
**Harvest:** late spring to late summer
◑ ◊ ☼

# Legumes: beans

**Runner bean '*Butler*'**
This attractive, red-flowered runner bean grows vigorously and forms many long, stringless pods filled with pretty purple beans. They can be picked over a long season and, being stringless, are still palatable when a little larger.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**Runner bean '*Liberty*'**
A favorite with exhibitors, this runner bean has glorious scarlet flowers followed by extremely long (up to 18 in/45 cm) pods. The heavy crops of smooth-skinned pods are prized for their tasty, thick flesh.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**Runner bean '*White Lady*'**
The pure white flowers of this runner bean are thought to be less attractive to birds. Hot weather can prevent pods from setting on other varieties, but 'White Lady' still performs well, making it suitable for later sowings.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**Runner bean '*Wisley Magic*'**
A runner bean with bright red flowers that develop into slim pods up to 14 in (35 cm) long, with a delicious fresh flavor. The plants grow rapidly and produce good yields, but pods are not stringless so are best harvested young.

**Sow:** mid-spring to early summer
**Harvest:** midsummer to mid-fall

**French bean '*Purple Queen*'**
Perfect for a container or border, this compact dwarf French bean grows without supports and develops heavy crops of glossy, rich purple pods. The stringless pods have a fine flavor and turn green when cooked.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**French bean '*Delinel*'**
A dwarf bean for a bumper crop. In containers or beds, it produces large yields of rounded, long green beans with a firm texture and good flavor. Plants are resistant to common bean mosaic virus and anthracnose.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**French bean '*The Prince*'**
This dwarf variety has long, flat, green pods, best harvested young when they are stringless. The flavor is excellent, and crops can be reliably harvested by early summer. They are also produced over a long period.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**French bean '*Ferrari*'**
A fine dwarf French bean—slim, succulent, bursting with flavor, and stringless. The plants do well sown in mid-spring if protected from frost, and thrive in containers. The connoisseur's choice, as well as easy to grow.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**French bean '*Cobra*'**
Train up a teepee or trellis to achieve large crops of stringless, tender green beans, up to 8 in (20 cm) long. The flowers are an unusual shade of violet, which make the plants ornamental as well as productive.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**Borlotto '*Lingua di Fuoco*'**
Grown in the same way as a climbing French bean, this Italian cranberry bean has long, flattish, pale green pods marked with red. Eat whole when young or remove the purple-blotched seeds from mature pods and dry them.

**Sow:** mid-spring to midsummer
**Harvest:** early summer to late fall

**Fava bean '*Aquadulce Claudia*'**
An old favorite, this hardy fava bean can overwinter outdoors. Plants grow to 3 ft (90 cm) and yield a good crop of tender white beans in "cotton gauze" lined pods. Black bean aphid is often a pest on shoots.

**Sow:** mid- to late fall; mid- to late winter **Harvest:** late spring to early summer

**Fava bean '*The Sutton*'**
Compact and bushy, this fava bean reaches only 18 in (45 cm), so is ideal for small gardens and for sowing under cloches in late winter and on windy sites. It produces abundant small pods packed with juicy white beans.

**Sow:** midwinter to early spring
**Harvest:** early to late summer

# Fruiting vegetables: tomatoes

**Tomato '*Totem*' F1**
A dwarf upright bush variety that is the perfect size for patio containers and large window boxes. It crops well outdoors: by midsummer, its trusses are heavy with small, tasty red fruits.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early spring to mid-spring **Harvest:** midsummer to mid-fall ♢ ◑ ☼

**Tomato '*Tumbler*' F1**
Ideal outdoors in hanging baskets or large containers, this bush tomato has stems that trail attractively over the side of a pot. It provides a prolific crop of sweet, red cherry tomatoes.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early spring to mid-spring **Harvest:** midsummer to mid-fall ♢ ◑ ☼

**Tomato '*Early Bush Cherry*'**
Easy to grow and quick to ripen, this bush variety does well outdoors in containers, or in a greenhouse. Its huge numbers of small, round, cherrylike fruits have a sweet flavor.

**Sow:** (indoors) midwinter to mid- spring; (outdoors) early spring to mid-spring **Harvest:** midsummer to mid-fall ♢ ◑ ☼

**Tomato '*Sungold*' F1**
Masses of incredibly sweet, orange cherry tomatoes make this a popular variety. It is a cordon tomato, so needs staking and side-shooting. It grows well under glass or outdoors.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early spring to mid-spring **Harvest:** midsummer to mid-fall ♢ ◑ ☼

**Tomato '*Sweet Olive*' F1**
For baby plum tomatoes that grow outdoors, try this reliable cordon variety. The clusters of scarlet fruits have an excellent, intense flavor, and the skins do not split readily. Plants may require some staking.

**Sow:** early to mid-spring **Harvest:** midsummer to mid-fall ♢ ◑ ☼

**Tomato '*Shirley*' F1**
This dependable greenhouse variety yields heavy crops of large, rounded, scarlet fruits, even in poor weather conditions. A cordon variety, it requires staking and side-shooting, but has some disease resistance.

**Sow:** midwinter to early spring **Harvest:** early summer to early fall ♢ ◑ ☼

**Tomato '*Tigerella*' F1**
Unusual red fruits striped with yellow make this variety stand out, but they also taste delicious and mature early. A cordon tomato that crops well indoors and outside.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early spring to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

**Tomato '*Gardener's Delight*'**
Perfect for a sheltered spot outside or a greenhouse, this is an extremely popular cordon tomato variety because of its bumper crops of fine-flavored, large cherry tomatoes.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

**Tomato '*Ferline*' F1**
An excellent cordon tomato producing large, rounded, red fruits, with increased blight tolerance. Plants grow well inside or out, and the fruits have a rich flavor.

**Sow:** (indoors) midwinter to mid-spring; (outdoors) early to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

**Tomato '*Supersweet 100*' F1**
For long trusses of juicy, sugary, scarlet fruits, this is a great variety to try under glass. With good resistance to verticillium wilt, these vigorous cordon plants are easy to grow and yield reliably generous crops.

**Sow:** midwinter to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

**Tomato '*Super Marmande*'**
This variety has a bushy habit, but benefits from some support. The large fleshy, puckered fruits are bursting with flavor and are a favorite in France. Plants thrive outdoors in warm areas.

**Sow:** midwinter to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

**Tomato '*Summer Sweet*' F1**
An early plum tomato for a sunny spot outdoors or in a greenhouse, this cordon variety yields plenty of small, tasty, red fruits over a long season. Plants have resistance to fusarium to help ensure a good crop.

**Sow:** midwinter to mid-spring **Harvest:** midsummer to mid-fall ◊ ◑ ☼

# Fruiting vegetables: eggplant, peppers, sweet corn

**Eggplant '*Moneymaker*' F1**
This is one of the most dependable eggplants in cool climates. The upright plants look good in containers, and while the best long, dark purple fruits are achieved under glass, plants also do well in a sunny outdoor spot.

**Sow:** early to mid-spring
**Harvest:** midsummer to early fall

**Eggplant '*Black Beauty*'**
A prolific variety, producing many glossy, deep purple, oval-shaped fruits. The highest yields are achieved with the protection of a greenhouse. Plants are best tied to supports to help bear the weight of the fruits.

**Sow:** early to mid-spring
**Harvest:** midsummer to early fall

**Eggplant '*Mohican*'**
With its compact bushy habit and immaculate white fruits, this eggplant makes a striking container plant for a sunny patio or greenhouse. Plants reach only 24 in (60 cm). Pick the fruits small to increase the yield.

**Sow:** early to mid-spring
**Harvest:** midsummer to early fall

**Pepper '*Gypsy*' F1**
Good, early crops are reliably produced by this sweet pepper, which performs well under glass. Tapering fruits ripen to bright red from yellow-green and have thick, succulent flesh. Plants are resistant to tobacco mosaic virus.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall

**Pepper '*Marconi Rosso*'**
The elongated fruits of this pepper are best eaten when red, because at this stage they are extremely sweet and ideal for roasting. Plants are high-yielding indoors or in a warm, sunny spot outside.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall

**Pepper '*Corno di Torro Rosso*'**
Delicious, long, thin-walled peppers are sweet once they have turned to purple and red. This early variety appreciates the extra heat in a greenhouse, but crops outdoors in warm areas.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall

**Pepper '*Hungarian Hot Wax*'**
An attractive, compact chili pepper bearing tapering fruits that are sweet and yellow when young, but hot and bright red when mature. The best crops are achieved with the protection of a greenhouse or large cloches.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall
💧 ☼

**Pepper '*Prairie Fire*'**
These tiny, bullet-shaped peppers are extremely fiery and look decorative pointing up from the bushy plants, which reach no more than 8 in (20 cm) tall. Ideal for windowsills or against a sunny wall. Plants crop heavily.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall
💧 ☼

**Pepper '*Friar's Hat*'**
Best grown in a greenhouse, these tall plants produce heavy yields of bizarre peppers shaped like sun hats. Plants need staking, while fruits need a long, hot growing season to ripen and build up a hot chili flavor.

**Sow:** early to mid-spring
**Harvest:** midsummer to mid-fall
💧 ☼

**Sweet corn '*Butterscotch*' F1**
A super-sweet mid-season variety, forming large cobs up to 8 in (20 cm) long that are filled with tender, sugary, butter yellow kernels. Grows vigorously and crops well even in cool weather conditions.

**Sow:** mid- to late spring
**Harvest:** late summer to early fall
💧 ☼

**Sweet corn '*Indian Summer*'**
These spectacular multicolored cobs have sweet-tasting kernels in shades of yellow, cream, red, and purple. Keep the plants separate from other sweet corn varieties to prevent cross-pollination and maintain the colors.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall
💧 ☼

**Sweet corn '*Lark*' F1**
This variety consistently produces a high proportion of healthy seedlings from each sowing, and is ideal for beginners. The sweet, tender cobs are delicious when boiled briefly and topped with melted butter.

**Sow:** mid- to late spring
**Harvest:** late summer to mid-fall
💧 ☼

# Perennial/stem vegetables: asparagus, artichokes, celeriac, celery

**Asparagus '*Connover's Colossal*'**
A traditional variety that yields a heavy crop of thick green spears early in the season. Buy young crowns and try not to harvest in their first year—just cut a few spears in the second and reap the reward in the third.

**Plant:** late winter to early spring
**Harvest:** late spring
☼

**Jerusalem artichoke '*Fuseau*'**
This relative of the sunflower produces long, smooth tubers, with a flavor similar to globe artichokes, which are usually eaten cooked. Plants may reach 10 ft (3 m) in height, each yielding about 10 tubers.

**Plant:** late winter to late spring
**Harvest:** early to late winter
◑ ☼

**Globe artichoke '*Green Globe*'**
Often difficult to find in stores, but easy to grow, this reliable globe variety has large flowerheads with delicious, tender hearts. Grow from offsets where available.

**Sow:** late winter to early spring
**Plant offsets:** late spring to early summer **Harvest:** late spring to early summer ◑ ☼

**Celeriac '*Monarch*'**
Easier to grow than celery, with a milder flavor, celeriac is delicious raw, steamed, or roasted. This cultivar has unusually smooth skin, making it easier to clean than most, and has fine-textured, creamy flesh.

**Sow:** early to mid-spring
**Harvest:** mid- to late fall
◑ ☼

**Celery '*Victoria*' F1**
The attractive pale green stems of this variety have a particularly good flavor and crispness. There is no need to earth up the stalks to blanch them, and the plants are slow to bolt.

**Sow:** late winter to mid-spring
**Harvest:** late summer to mid-fall
◑ ☼

**Celery '*Celebrity*' F1**
An excellent self-blanching variety that grows equally well outdoors or in a greenhouse. The light green stems have a delicious, strong flavor, and plants resist bolting well.

**Sow:** late winter to mid-spring.
**Harvest:** late summer to mid-fall
◑ ☼

# Herbs

**Parsley '*Plain Leaved 2*'**
A fine French parsley, with soft, flat, rich green leaves that have a good, strong flavor. Easily grown as an annual indoors or outside, although parsley is biennial and hardy enough to persist in most gardens.

**Sow:** early spring to late summer
**Harvest:** year round

**Parsley '*Envy*'**
Handsome and vigorous, this variety produces a mass of tightly curled, bright green, full-flavored leaves. Parsley seeds may be slow to germinate, but be sure that the soil is soaked after sowing.

**Sow:** early spring to late summer
**Harvest:** year round

**Basil '*Sweet Genovese*'**
Large-leaved and intensely aromatic, this is the basil to use in Italian dishes. The tender plants will grow in a sunny spot outdoors, but often do best on a bright windowsill or in a greenhouse. Pinch out young leaves regularly.

**Sow:** early spring to midsummer
**Harvest:** year round

**Basil '*Magic Mountain*'**
With its glossy, purple-tinted foliage and tall spikes of lilac flowers, this tender herb makes a pretty garden plant in its own right. The leaves have a delicate aniseed scent, which makes them suitable for Thai cooking.

**Sow:** early spring to midsummer
**Harvest:** year round

**Thyme '*Silver Posie*'**
The tiny gray and cream leaves of this compact and low-growing thyme are intensely fragrant, complementing the flavors of chicken and fish. An evergreen hardy perennial, it has clusters of pink flowers in summer.

**Sow:** early to late spring
**Harvest:** year round

**Thyme '*Doone Valley*'**
The vibrant yellow variegation of this thyme's evergreen foliage, combined with a flush of purple summer flowers, makes it a beautiful plant for a pot or herb garden. The lemon-scented leaves taste good with fish or in stews.

**Sow:** early to late spring
**Harvest:** year round

# Herbs and sprouting seeds

**Oregano (*Origanum vulgare*)**
A pungent Mediterranean herb often used in Italian cuisine and reliably perennial in freely draining soil. Its rounded, yellow-green leaves and low-growing habit make it an attractive garden plant, useful for edging paths.

**Sow:** early to late spring
**Harvest:** year round

**Rosemary (*Rosmarinus officinalis*)**
This shrub bears the tough, narrow, strongly scented leaves that combine so well with lamb. As an evergreen, rosemary provides useful structure in the herb or vegetable garden, and can be pruned to maintain its shape.

**Sow:** early to late spring
**Harvest:** year round

**Fennel (*Foeniculum vulgare*)**
Elegant and airy, fennel comes in green and bronze forms and may reach 6 ft (1.8 m) tall. It is a good-looking perennial in ornamental borders, where its aniseed-flavored leaves, and later its seeds, can be harvested as required.

**Sow:** early to late spring
**Harvest:** late spring to early fall

**Apple mint (*Mentha suaveolens*)**
Delicious, but invasive, this mint is best confined to a pot in small gardens. It is perennial and each spring sends up new shoots clothed with soft, furry, sweetly minty leaves, perfect for cooking with new potatoes.

**Sow:** early to late spring
**Harvest:** late spring to late summer

**Spearmint (*Mentha spicata*)**
Spearmint's clean, crisp flavor is ideal for adding to salads, desserts, and drinks. The pointed, deep green leaves are glossy and appealing, but this is also an invasive perennial, so keep its spreading shoots in check.

**Sow:** early to late spring
**Harvest:** late spring to early fall

**Chives (*Allium schoenoprasum*)**
The clumps of these easy-to-grow perennials have spiky leaves topped with purple pompon flowers, making them an excellent path edging. The delicate onion flavor of chives suits soups, salads, and quiches.

**Sow:** early to late spring
**Harvest:** at any time

**Cilantro '*Cilantro for Leaf*'**
A lush, leafy annual, bred to yield several cuts of spicy leaves, rather than seeds. Sow successionally every six weeks to ensure a constant supply and keep plants well watered to stop them from rapidly running to seed.

**Sow:** mid-spring to early fall
**Harvest:** early spring to early fall
☼

**Common sage (*Salvia officinalis*)**
Ornamental, with many culinary uses, this aromatic shrub has pale green leaves covered in an attractive gray down. Encourage bushy growth by pinching out growing tips, but replace old plants every five years.

**Sow:** mid- to late spring
**Harvest:** at any time
☼

**Lemon grass (*Cymbopogon citratus*)**
Tropical and tender, this grass needs to be kept above 45°F (7°C) in winter. The sturdy, citrus-scented stems can be slow to bulk up in cool climates, but form clumps from which stems can be separated and used in Thai dishes.

**Sow:** mid- to late spring
**Harvest:** late spring to early fall
☼

**Alfalfa**
A nutritious, crisp sprout, with a slightly nutty flavor, alfalfa is delicious in salads and sandwiches. Soaking the seeds for eight hours before sprouting helps speed up the process. Sprouts should be ready from trays or jars in 4–5 days.

**Sow:** at any time
**Harvest:** at any time

**Mung beans**
These tiny green beans burst rapidly into life to become the well-known white Chinese bean sprouts, so often included in stir-fries. Soak the beans for 8–12 hours, before sprouting in a jar, tray, or sprouting bag for 2–5 days.

**Sow:** at any time
**Harvest:** at any time

**Garbanzos**
Sprouted garbanzos (chickpeas) are a tasty snack or addition to a salad and require only 2–3 days in a jar, tray, or sprouting bag before they are ready to eat. Soak them in water for 8–12 hours before sprouting, to ensure that the seed coat is softened.

**Sow:** at any time
**Harvest:** at any time

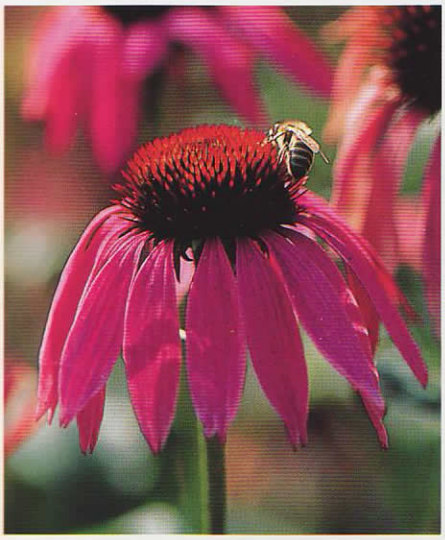
# INTRODUCTION

The aim of this book is to show that organic gardening is gardening at its best. The most successful organic gardeners learn that the use of artifical chemicals for short-term gains leads to long-term losses and also that nature makes the best model. Whether you want to grow organic produce for your table, have a dazzling display of summer colour or create a wildlife paradise, the organic garden is for you. Many techniques may already be familiar to you and the change will be less difficult than you think. Going organic may not change the world immediately, but being an organic gardener means that you can make a difference to the wellbeing of the world.

Left: *A well-maintained ornamental garden will reward the keen organic gardener with a wealth of dazzling colour.*



Above: *Organic gardens are highly beneficial to wildlife because they mimic natural environments.*

Above: *The organic garden is the ideal place in which to grow a selection of fresh healthy vegetables.*

Above: *Ornamental plants and flowers are perfectly at home and thrive in a garden that uses organic principles.*

# WHAT IS ORGANIC GARDENING?

*The term organic means of living origin. When applied to gardening, organic has come to mean the systematic use of techniques that mirror naturally occurring systems. Put simply, it is about finding environmentally friendly ways to cultivate the land, working with rather than against nature. Organic gardening refers not just to a system of techniques, however, but also to a whole philosophy of life.*

Above: *The organic garden uses a range of natural materials, including by-products such as chicken manure.*

## THE ORIGINS OF ORGANIC GARDENING

From the point of view of gardening, the "modern" organic movement began in the late1940s as a reaction to the increased use of pesticides and synthetic fertilizers in the years after the Second World War. In many respects, however, the principles of organic gardening have been practised for centuries. Ancient writers, among them Pliny and Virgil, commented on the importance of "good husbandry to the health of the land". Thomas Tusser, in his classic work of 1580 entitled *Five Hundred Points of Good Husbandry*, recommends crop rotation to maintain good health. The 17th-century English garden writer John Evelyn begins his *Kalendarium Hortense* with a section describing how to enrich the ground in mid-winter with "horse and sheeps dung especially, that you may have some of two years preparation".

Above: *Many of the plants that benefit wildlife also make showy and decorative additions to beds and borders.*

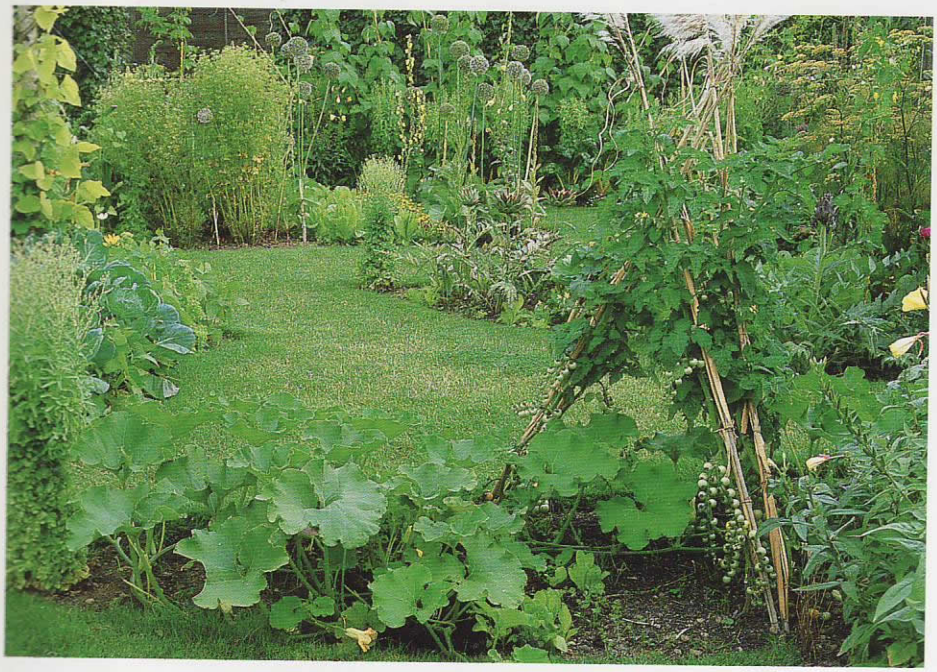
## ORGANIC GARDENING IN THE 21ST CENTURY

Much of the current interest in organic gardening began in the 1960s, when there was increasing concern about the growing levels of environmental damage caused by pesticides and other agrochemicals. If they were causing so much damage to the natural world, then surely they must ultimately affect human beings?

The organic approach aims to reduce the effects that our gardens, farms and cities have upon the wider natural environment. Activities such as recycling, using sustainably produced materials and avoiding pesticides and other harmful agrochemicals all help in this. Organic gardening is often described as being a more natural way to garden. This can make it appear to be somehow revolutionary. In many ways, however, organic gardening could be said to be counter-revolutionary. It aims to avoid artificial inputs and gains. Instead it draws from a vast resource of wisdom and experience amassed over 10,000 years. Much of the so-called conventional wisdom is, in fact, very recent. We only have to look back as far as our grandparents to see that they were naturally organic gardeners. Organic gardening then is the marriage of good horticultural practice to an awareness of our impact upon our surroundings.

## IS IT POSSIBLE TO BE WHOLLY ORGANIC?

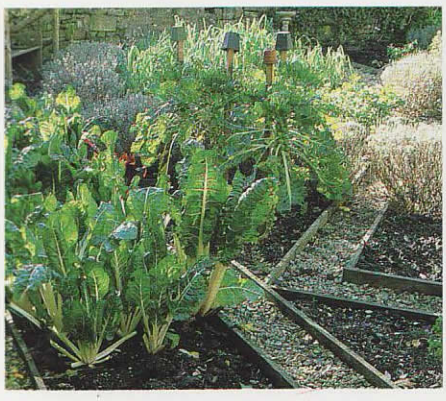
The short answer to this would probably have to be ... with great difficulty. But the purpose of this book is not to promote difficulty or set unattainable goals. The aim should always be to aspire to the ideal solution. Almost all of us face compromise on a daily basis and understand that practicalities outweigh personal ideals. With perseverance and practice, however, it is possible to become less compromised in the confines of your own garden. Simple planning and the observance of good



Left: *Organic gardens can be beautifully designed and can include a mixture of ornamental and edible plants.*

Above: *A well-designed and properly maintained organic garden can be both attractive and productive.*

gardening practice can steadily improve your organic credentials and, with time, a natural balance will be established in your garden. Ultimately, the aim of all organic gardeners, be they landscaping a city garden, tending a country estate or growing home-produced vegetables, is to make choices appropriate to their situation. It is better to move a few steps towards the organic way than to ignore it completely.



Above: *Vegetables need not be planted in rows. Here, the beds are arranged in an attractive geometric pattern.*

## ORGANIC STANDARDS

Organic standards are set out to explain the requirements that farmers, growers, processors and others must meet in order for their products or services to be marketed as organic. The standards can be extensive and cover a wide range of farming, growing and food manufacturing practices.

**Are organic standards the same worldwide?** No. Different countries may stipulate their own standards. IFOAM is the International Federation of Organic Agricultural Movements that represents the worldwide body of organic agriculture and provides a platform for the global exchange of information and co-operation.

**Are any chemicals allowed in organic production?** Yes. In line with the legal framework of the country, a very limited number of chemicals are allowed on a restricted basis. Organic standards do not allow the use of artificial herbicides or fungicides. By comparison, in non-organic farming as many as 450 chemicals can be routinely used.

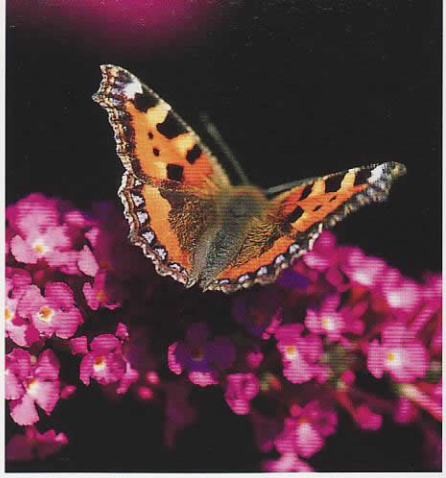
**If organic gardening severely restricts the use of artificial chemical fertilizers and pesticides, then how do I keep my garden healthy?** Organic gardeners rely on developing a healthy fertile soil and growing a mixture of crops. By following these basic practices, organic gardeners work in harmony with nature and aim to achieve a healthy natural balance within their gardens.

**Do I have to achieve any standards to become organic?** No. Commercial standards are very strict and not necessarily easy to achieve for the amateur. Everyone must make choices appropriate to their own situation.

**Is the organic movement just concerned with growing food?** No. Going organic is not just about organic food – it should become a way of life. Today, organic wood, clothing, gardening products and even restaurants can all be found. This means that other areas of your life can be organic as well as your garden. It does not always mean completely changing your life, but it can change lives.

# WHY GO ORGANIC?

*This commonly asked question is easy to answer. The primary reason to embrace the organic approach is health. This means the well-being of the individual as well as the health of the environment. Many pesticides can accumulate over time, both in our own bodies and in the wider environment, a poisonous legacy that can persist for decades. Organic gardening seeks to redress this damage by working with and encouraging nature. It is a long-term investment in the health and wellbeing of us all.*



Above: *Butterflies are just one of the many different types of wildlife that can benefit from a pesticide-free garden.*

## GREEN CUISINE

Hardly a day seems to go by without some new revelation about the benefits or detrimental effects of some food or other. Recent concerns about the "goodness" of the things that we eat have been a major incentive to supermarkets to supply a growing demand for organic produce. There can be little that equals the satisfaction to be derived from eating home-produced food, gathered fresh from the garden. What better than garden-fresh vegetables that are produced naturally and cleanly?

## A GREENER, SAFER GARDEN

Although we think of our gardens as places of safe retreat we have used a cocktail of pesticides and agrochemicals on them that has stripped them of their natural diversity. Many of these poisons no longer control the beasts that they were intended to. All that suffers in this noxious onslaught is the garden, its wild occupants and ultimately the plants. This cycle of pesticide use eventually turns your personal paradise into a potential health hazard.

## HELPING THE ENVIRONMENT

For many of us it can seem that there is little that we can do to change the degradation of our environment. But the truth is that the actions of all of us have both positive and negative impacts upon the land. If every individual reduces his or her own negative impact upon the environment, then collectively we can make a difference. By changing the way you garden to a more organic way, you can begin the healing process, literally in your own backyard.

## PROTECTING AND ENCOURAGING WILDLIFE

Be it a bird on a feeder or brightly coloured butterflies on a flower, most of us enjoy seeing visitors from the wild in our gardens. But many of the unsung heroes of our gardens – the insects, worms, amphibians and mammals that crawl, slither and scurry out of sight – are equally important and may even be the reason why some of the larger visitors come. Organic gardening helps many of these and promotes a balance of wildlife that is both interesting and beautiful to look at.

## SO WHAT IF I DO NOT GO ORGANIC?

While the intention of this book is not to dwell upon negative points, the cost of not adopting an organic approach may be seen all around us. This is most frequently noticed as fields and open spaces bereft of butterflies, bees, birds and other wildlife with very little diversity of plant species. It is unthinkable that we could hand this planet to successive generations in a denuded and impoverished state. Perhaps a garden free of "bugs" may sound attractive to some, but the long-term cost to the environment may be felt for generations and in the worst case may even be permanent.

Above: *Organic flower gardens, with their wide range of wildlife-friendly plants, can provide a balanced habitat for birds and insects that is diverse, interesting and beautiful to look at.*

Above: *Imaginative planting designs can result in beautiful contrasts of flowers and foliage, while also providing a wealth of flavourful, home-grown food for your table.*

## IT'S A SOLUTION AND IT'S FUN!

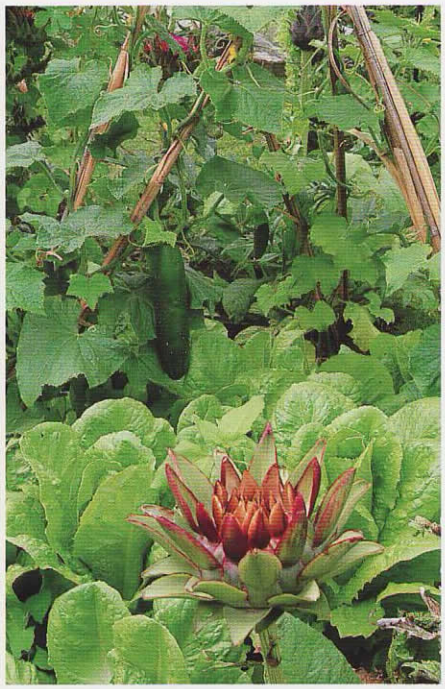
Organic gardening is not the solution to all humankind's problems. However, it is a positive and valuable step that you as an individual can take. What's more, you can contribute positively to the wellbeing of your surroundings and to that of your wider environment by doing something that is also fun and rewarding.

## WILL "GOING ORGANIC" MEAN THAT MY WHOLE LIFESTYLE HAS TO CHANGE?

Organic gardening is often presented as part of a more general "organic movement". This movement owes its origins to a range of social philosophies, some of which are more fundamentalist than others. The aim of organic gardening is to change the way that you garden and not your whole life. People frequently get confused about the meaning of words that are used as part of the wider organic movement. Four of these terms are explained below. Of these, three describe a whole philosophy that affects practitioners far beyond the confines of their own gardens. An understanding of the philosophies of others can help inspire your own lifestyle changes and all have their own points of interest. In the end, however, it is a matter of choice for you alone and it is best to decide just how organic you (and your family) wish to be.

**Biodiversity** literally means "the variety of life". It includes all the different plant, animal, fungus and microscopic species in the world. It also considers the genes they contain and the ecosystems of which they form a part. Biodiversity has been seen as the total complexity of all life, including not only the great variety of organisms but also their varying behaviour and interactions. An organic garden aims to maximize all these many different things which are vital to every part of the garden, but especially important when considering the soil. Soil biodiversity is the "lifeblood" of the organic garden and demands investment in order to yield a return.

**Biodynamics** is described by its practitioners as a science of life forces, recognizing the basic principles at work in nature and taking into account how our actions can bring balance and healing to the world. It is based upon the work of Rudolf Steiner and is said to offer an account of the spiritual history of the Earth as a living being. Its enthusiasts advocate a broadening of personal perspective that includes an understanding of cosmic rhythms, natural healing, a respect for life forces and ultimately a shift away from centralized economic strategies.



Above: *The foliage and form of many types of vegetables can provide striking contrasts in the vegetable garden.*

**Permaculture** is a concept that was originally developed in the 1970s by Australians Bill Mollinson and David Holgreen. It was conceived as a response to increasing concerns over the deteriorating natural environment. They attempted to answer the question "how do we, as the human species, sustain ourselves and provide for the needs of the environment for an indefinite period of time?". The answer to this question is the basis for creating a permanent culture (Perma-Culture). This philosophy aims to unite practical, ecological design philosophies by incorporating natural systems and materials into human habitats. Permaculture rejects short-term gains in favour of long-term stability for the environment and those who live in it.

**Self-sufficiency** is an ideal rather than a reality for most that attempt it, as modern living usually dictates some degree of trade, even if it is limited. Advocates of self-sufficiency aim to produce everything that they need in order to support themselves. The only imports are those that cannot be produced by an individual.

### REASONS FOR GOING ORGANIC

Below are just a few of the positive benefits that organic gardening may bring to you and your environment.

**Human impact on the earth** Organic systems reduce dependence on non-renewable resources. The world has an increasing population, but many of our resources are in limited supply. Using renewable resources helps to secure our common future.

**Traditional methods with modern techniques** Organic systems rely on a modern, scientific understanding of ecology and soil science. They also depend on traditional methods of crop rotation to ensure soil fertility as well as weed and pest control.

**Local solutions to global problems** The organic movement encourages individuals to act on a local level, while thinking about how this affects the world.

**Best for biodiversity** Organic growing is friendlier to the environment, so there is a greater diversity of birds, butterflies and plants in organic gardens.

**Minimize your waste** We produce a huge amount of waste, including packaging and kitchen and garden waste. Recycling and waste reduction are key issues for organic living.

**Mimicking natural systems** Organic gardening uses nature as its model and, by working in harmony with nature, aims to achieve a natural balance. By maintaining this equilibrium, organic gardens become very stable entities.

**A more interesting garden** Organic production is more sustainable and friendlier to the environment. By becoming involved in the whole natural cycle, you will gain greater satisfaction from your own personal Eden.

**We are what we eat ...** Organic systems recognize that our health is connected to the quality of our food and, ultimately, to the health of the soil.

# UNDERSTANDING YOUR GARDEN

*Plants, like all living things, flourish when given the right conditions. Certain plants will only thrive in a hot, sunny and dry garden, for example, while others may need cool, moist and shady conditions to prosper. If you are to have healthy plants, you need to choose those that are best suited to your garden and this means understanding exactly what conditions prevail and taking into account a range of environmental factors.*

Above: *A hot, sunny spot is ideal for growing pretty summer flowers such as argyranthemums and verbenas.*

## CLIMATE

The climate causes a variety of responses, depending upon the plant's location, its stage of maturity, the length of exposure and the intensity of the type of weather. Climate may have a dramatic effect on plant growth and development, especially when extreme weather conditions prevail.

## TEMPERATURE

All plant species have their own maximum and minimum temperature tolerances, beyond which the life processes of the plant cease. As a general rule, the maximum temperature that most plants can tolerate is around 35°C (95°F), while the minimum is highly variable. The air and soil temperatures are also crucial in influencing dormancy within plants and this, in turn, largely dictates the length of the growing season.

Air temperature is affected by the degree of energy received from the sun. A sheltered site that benefits from the warming effects of the sun may be used for growing plants that are indigenous to warmer climates.

Soil temperature influences a plant's root development and the rate at which water and nutrients can be absorbed. Sandy soils warm up quicker and earlier in the season than clay soils, mainly because they are relatively free draining and do not hold as much water. Sites that receive a lot of sun, or with a slight incline towards it, will also warm up quicker than shady ones.

## WATER

This is the major constituent of all plants. In most gardens, rainfall is the principal source of water for plants and it can be lost through evaporation or surface run-off, although much of it is soaked up by soil particles. This water may then be absorbed by the root hairs of the plant. A steady supply of water is essential for the plant to sustain itself and for optimum growth.

Water may also be held in the air and is referred to as humidity. The amount of water vapour in the atmosphere at any one time is referred to as the relative humidity and is measured as a percentage of the saturation point (100 per cent humidity). In areas that receive heavy rainfall, relative humidity is also higher. Many plants, such as ferns and mosses, thrive in such conditions. But high relative humidity can have undesirable effects on plants, often encouraging disease.

Waterlogging refers to the build-up of water that may occur in badly drained soil with poor structure. The roots of plants that are not adapted to these conditions will suffer and probably die through asphyxiation.

Left: *A bog garden provides ideal conditions for a range of decorative moisture-loving plants.*

Right: *Blossom is both pretty and essential for good fruit-set. A sheltered site will also encourage pollinating insects.*

## LIGHT LEVELS

Sunlight enables photosynthesis (the method by which plant food is made) to occur. As a result, it is vital to new growth as well as sustaining existing growth. Seasonal changes in light levels may also trigger different stages in the plants' development.

## AIR CIRCULATION

Even moderate winds can increase a plant's transpiration rate. However, a light wind can also have beneficial effects, providing relief from extreme heat and cooling the foliage. It will also "change the air" around the plant and thus help to alleviate a stagnant atmosphere that could promote disease.

## ASSESSING THE CLIMATE

A range of climatic information is generally available for your local region. Weather forecasts are an obvious source, but long-term records are sometimes available. From these you should be able to get a picture of the average rainfall, snow, frosty days, wind direction and monthly temperatures.

## A TYPICAL GARDEN AND ITS MICROCLIMATES

*Even a small garden can contain a wide variety of microclimates, ranging from cool, shady corners to hot, dry areas. A proper assessment of the growing conditions that prevail in your garden allows you to choose the right plants for the right place.*

### A GARDEN'S MICROCLIMATE

The prevailing weather conditions in confined or discrete areas are termed the microclimate. For example, there will be a range of environments within a small domestic garden that may be very different from those weather conditions prevailing elsewhere in the locality. Observe what is going on in your own garden and keep a careful record of the position and influence of the following features.

**Walls, hedges and fences** may cause wind turbulence and dryness, depending upon their height and density. They may cause cold air to build up on sloping sites by preventing it from "draining away" downwards. This can create frost pockets that may have a crucial effect on the type and range of plants that may be grown.

**Shadow projections** from permanent features, such as buildings, walls, hedges and large trees, may create a range of dense shadow resulting in dark, dry and often cool conditions that will only suit certain plant species.

**Hot spots** may occur with aspects that are subject to high and prolonged levels of sunlight. Plants may struggle in the dryness created by such strong sunlight.

**Damp areas** may be anticipated where the ground is low-lying, especially on very heavy soils. During heavy rainfall you should also note the direction of water flow, including where necessary the route taken by excess surface water, which may in extreme cases be the cause of soil erosion.

**Soil type and pH** play an important role in the ability of a site to support particular plant species. The relative acidity or alkalinity can affect the availability of certain essential nutrients, leading to either shortage or toxicity in plants not ideally suited to the pH of a soil. It is always better to choose plants that thrive in the particular pH of a soil. Attempts to alter the pH by acidifying or adding lime are rarely satisfactory and neither are long-term solutions.

**Existing habitat** types on and around the garden indicate what plants are likely to thrive. Notes should be made on the range of species and the likely wildlife value.

**The garden topography** (the shape and aspect of the land) may also affect what you are able to do. If a garden slopes toward the direction of the midday sun, for instance, it will be warmer than a flat site. Sloping or uneven gardens have their own problems, particularly if you wish to site a greenhouse.

### RIGHT PLANT, RIGHT PLACE

Once you have assessed your garden environment, you will be able to choose the right plants for your site. Every garden has its own unique set of advantages and limitations, and these take time to evaluate, so trial and error is ultimately the most reliable method.

Right: *A shady corner of the garden provides the perfect place for shade lovers such as these foxgloves (*Digitalis*).*

# THE ORGANIC CYCLE

*Plants produce their own food using carbon dioxide from the air, water from the soil and energy from the sun in a process known as photosynthesis. The energy in this sugar powers all the growth, development and life-giving processes within the plant. Plants must also produce a range of other substances, including proteins, fats, oils and cellulose, for which they need nutrients such as nitrogen, phosphorus, and potassium. These are almost always taken up through the roots.*

Above: *Plant leaves are remarkable structures because they are the factories in which a plant makes its food.*

## WHAT PLANTS NEED

In natural systems, nitrogen, phosphorus and potassium are repeatedly taken up by the plant, used and returned to the soil when the plant dies, drops its leaves or is eaten by an animal. This process is known as nutrient cycling. Plant nutrients are covered in more depth later. For now we need only look at three of the most important cycles: water, carbon and nitrogen.

## THE WATER CYCLE

The movement and endless recycling of water between the atmosphere, the surface of the land and under the soil is called the water cycle and is driven by the energy of the sun and the force of gravity.

Water vapour in the atmosphere condenses into clouds, which fall as snow, rain, sleet or hail. This water may be taken up by plants, stored in lakes, enter the soil or flow over the surface in streams. The sun causes water to evaporate back into the atmosphere, or gravity may pull it down through the pores of the soil to be stored as slow-moving ground water. Water can also return to the atmosphere indirectly through plants' leaves – a process known as transpiration – this being highest during periods of high temperatures, wind, dry air and sunshine.

Above: *Plants rely on water, taken up through the roots, to support their life processes and facilitate growth.*

## THE CARBON CYCLE

The movement of carbon, in its many forms, between the total living content of the earth, the atmosphere, oceans, and the rocks and soils covering the surface, is termed the carbon cycle. It is complex and far reaching. The same carbon atoms in your body today have been used in countless other molecules since time began. Plants absorb carbon dioxide from the atmosphere during photosynthesis (food production) and release it back into the atmosphere during respiration (food use). This process is the great natural recycler of carbon atoms.

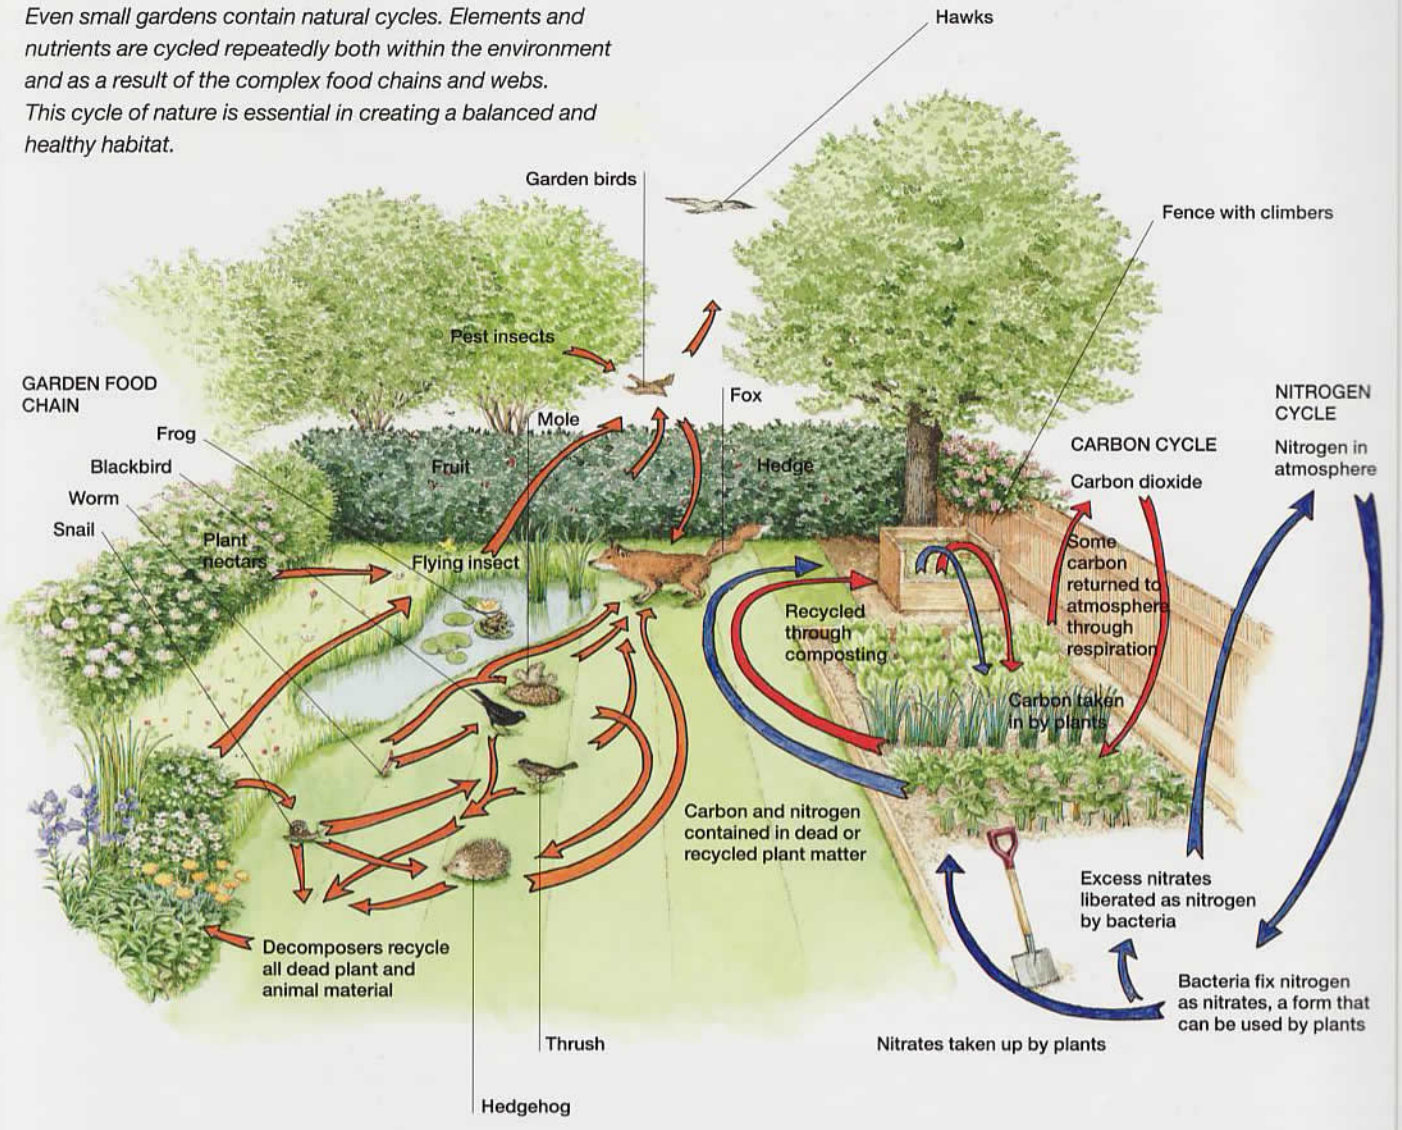
Right: *Left to develop naturally, grassland will become a rich and diverse habitat for a wealth of both plants and wildlife.*

## THE NITROGEN CYCLE

Nitrogen is used by living organisms to produce a number of complex organic molecules such as amino acids, proteins and nucleic acids, the "building blocks" of life. The largest store of nitrogen is in the atmosphere, where it exists as a gas. This store is about one million times larger than the total nitrogen contained in living organisms.

**NUTRIENT CYCLES IN A TYPICAL GARDEN**

*Even small gardens contain natural cycles. Elements and nutrients are cycled repeatedly both within the environment and as a result of the complex food chains and webs. This cycle of nature is essential in creating a balanced and healthy habitat.*



Despite its abundance in the atmosphere, plants can only take up nitrogen in two solid forms: ammonium and nitrate. Most plants fulfil their needs using nitrate from the soil. Ammonium is used less frequently because it is toxic in large concentrations. Most ecosystems have nitrogen stored in living and dead organic matter, which re-enters the cycle via decomposition. Decomposers in the soil, such as bacteria and fungi, chemically modify the nitrogen found in this organic matter.

Almost all of the nitrogen found in any terrestrial ecosystem originally came from the atmosphere and is biochemically converted ("fixed") into a useful form within the soil by specialized bacteria. Members of the bean family (legumes) and some other kinds of plants form relationships with nitrogen-fixing bacteria. In exchange for nitrogen, the bacteria receive food from the plants and special root structures (nodules) that provide protection.

## WHAT ARE ECOSYSTEMS?

Short for ecological systems, ecosystems are communities of plants and animals that consist of a given habitat (the place where an organism lives) and its community (all the plants and animals that live in it). Any group of living and non-living things interacting with each other (including those found in gardens) can be considered an ecosystem.

The chemical materials that are extracted from the environment and changed into living tissue by plants and animals are continually recycled within the ecosystem. These nutrient cycles are at their most efficient when an ecosystem has a good diversity of species. Such diversity tends to make a community stable and self-perpetuating.

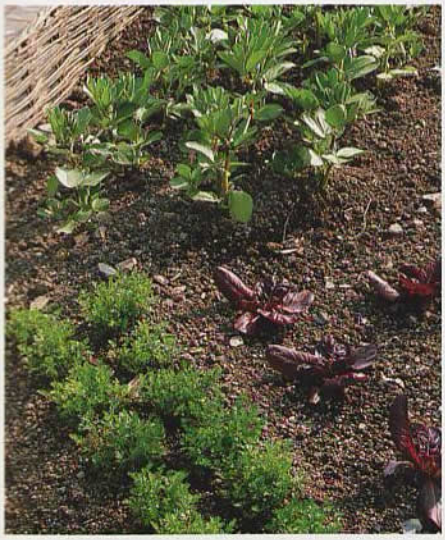
## FOOD CHAINS AND WEBS

The energy necessary for life reaches the earth as sunlight. This is made into food and stored in plants. Animals acquire some of the stored energy by eating the plants or by eating other plant-eating animals. Such sequences, called food chains, overlap at many points, forming food webs which show "who eats whom" in an ecosystem. If one animal or plant is affected, then the entire food web can be changed.

# SOIL AND SOIL MANAGEMENT

Soil is the most precious resource in your garden. Some inherit a well-tended soil, while others, particularly those moving into new homes, inherit a rubble-filled mass. However, any soil can be improved through time and effort. If you regard your soil as a living entity, you will see that essential plant nutrients are cycled by a microscopic army of inhabitants and larger worms, insects and grubs. All these creatures need air, moisture and food. Using manure, garden compost and other sources of organic matter is the key to sustaining this soil life and keeping the soil healthy.

Left: *The key to developing a successful organic garden lies in the careful management of the soil.*



Above: *Newly planted crops must be kept weed free so that water and nutrients are freely available.*

Above: *Companion plants can help to protect crops naturally from pests, thus avoiding damage to the soil ecology.*

Above: *Crops that are grown in rows must be rotated on a regular basis in order to avoid soil-borne pests and diseases.*

# TYPES OF SOIL

*Soil is probably the most important constituent of any organic garden because it is vital for successful plant growth. Understanding your soil and knowing how this can help you to create a healthy, fertile growing environment for your plants should be a priority. The starting point in this process is an understanding of the different soil types and how they affect the plants you can grow. Once you understand the soil in your own garden, then you will be able to create a successful organic garden.*

Above: *All soil types benefit greatly from the addition of organic matter such as this green manure.*

## WHAT ARE SOILS MADE OF?

Both natural soils and some potting mixes for container-grown plants usually have five main components. These are mineral particles (the inorganic fraction), organic matter (the remains of living organisms), water (the "soil solution"), air (which fills the spaces between solid particles that are not filled with water) and living organisms. The proportions of these components vary widely according to the soil type, or the growing medium.

The proportions of water, air and organic matter can be readily changed by soil cultivation and other horticultural practices. A good topsoil will continuously supply plant roots with water, air and nutrients. Subsoil (the largely inert soil layer that lies beneath the thin layer of "living" topsoil) has less organic matter than topsoil. Plant growth will suffer when the proportions of water and air in the medium are out of balance. Too much air will have the same effect upon plant roots as a drought, whereas too much water causes waterlogging. Growth will also suffer if nutrient levels are too low, too high or if there is an imbalance in supply between different nutrients. In addition, soil that is too compacted for roots to grow will also adversely affect growth.

## SAND AND SILT

Sandy and silty soils originate from river deposits, windblown sediments or from the erosion of sandstone outcrops. Their general properties are that they do not provide or retain plant nutrients; they are not cohesive and therefore possess a weak structure; and in most cases they are free draining.

Silts, unless well structured, will be waterlogged. Sand, on the other hand, is naturally free draining. The structure and texture of sandy soils means that they are only able to hold a very small reserve of water. Organic matter can improve the available water content but the real trick in avoiding drought-stress lies in ensuring that plants root deeply into the soil. Nutrient shortage can also be a problem on sandy soils which have a tendency to become acidic over time. Liming and the regular addition of organic matter will help alleviate these problems.

Sandy soils do have the advantage of "warming up" quickly in spring due to their lower water content and are easier to work early in the year. This means that you can grow a wider range of plants in a sandy soil. Planting or transplanting is also easier in the autumn.

Organic material is broken down very quickly in sandy soils due to good aeration and a temperature that favours rapid bacterial action. Many light soils naturally have less than two per cent organic matter and it is vital that organic matter be added regularly to sustain healthy plant growth.

### COMMON TYPES OF SOIL

**Sand** A free-draining soil that is quick to warm up, but hungry and thirsty.
**Silt** River deposits can be sticky, but not as sticky as clay. Rich and easy to work.
**Clay** A heavy soil that is often difficult to work. Slow to warm up, but fairly rich.
**Loam** A moisture-retentive soil that warms up quickly and works perfectly.

### PLANTS SUITABLE FOR DIFFERENT SOIL TYPES

Many plants have a type of soil in which they grow best. The list below gives a few examples of the soil preferences of some common species.

**Plants suitable for acid soils**
*Rhododendron* (all species)
*Camellia* (all cultivars)

**Plants suitable for alkaline soils**
Butterfly bush (*Buddleja* spp.)
Sage (*Salvia*)

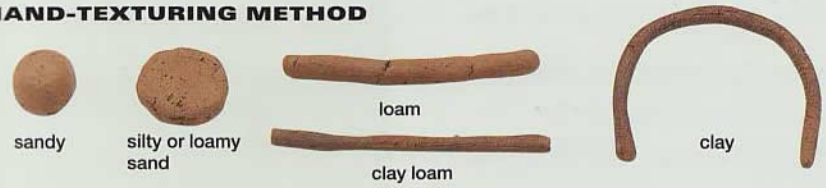
**Plants suitable for hot dry soils in sun**
Yucca (all species)
Broom (*Cytisus*)
Lavender (*Lavandula*)

**Plants suitable for damp or wet soils**
Willow (*Salix*)
Dogwood (*Cornus*)
Plantain lily (*Hosta*)

**Plants suitable for heavy clay**
*Weigela* (all cultivars)
*Crocosmia* (all cultivars)
Daffodil (*Narcissus*)

**Plants suitable for dry shaded soils**
Flowering currant (*Ribes sanguineum*)
*Pachysandra terminalis*
Elephant's ear (*Bergenia cordifolia*)

### HAND-TEXTURING METHOD



Finding out what type of soil you have is easy and does not require any specialist equipment. This test is ultimately a matter of judgement and will only give you a relative picture of the sort of soil you have. However, it is surprisingly accurate. Simply take a small amount of soil – about a teaspoonful will do – in the palm of your hand. Moisten with a little water (not too much but enough to make it just workable). Once moistened, try to form the soil into one of the shapes shown above.

1 Begin by forming a ball. If it stays together, then proceed to the next shape. If it does not form a ball, then you have a sandy soil.
2 If you can flatten the ball without it breaking up, then you have a silty sand or a loamy sand.
3 If you can roll the flattened ball into a thick sausage shape, then you have a loam.
4 A soil that can be rolled into a thin "sausage" is a clay loam.
5 If you can bend the soil into a horseshoe or ring shape, then you have a clay soil.

Above: *Plants such as alliums and eryngiums like well-drained soil and so will thrive together in the same site.*

## CLAY

The particles found in clay are extremely small and are able to interact with, and directly affect, the chemistry of the soil. The individual clay particles are so tiny that they are actually bonded together by electrical charges which produce the characteristic plasticity of this type of soil. Clay is both water retentive and rich in nutrients. It has few pore spaces and those that are there have a tendency to become waterlogged. Clay is prone to swelling when waterlogged and shrinkage when dry. As a result, clays heave (swell outward and upward) when wet and crack when dry. They can also be subject to frost action which causes an increase in tiny, almost microscopic, airspaces (micro pores). Pure clay soils are rare, although some soils may be very rich in clay. They have the potential to be extremely fertile soils if they are well managed.

## LOAMS

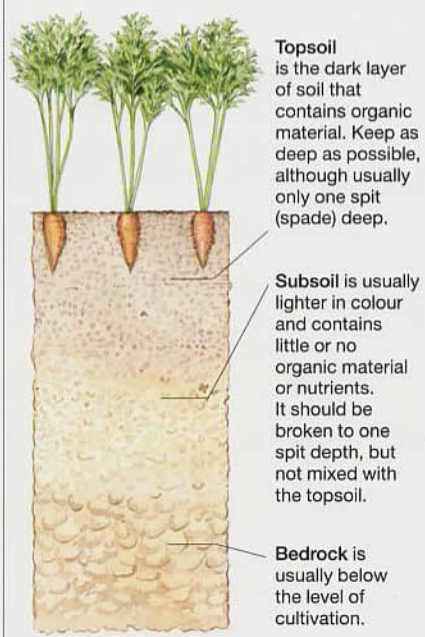
Loams are a mixture of sand, silt and clay that results in a blend of the characteristics of each constituent part. They are usually characterized by their clay content. Heavy loams are about 24–30% clay, whereas light loams contain about 12–18% clay. Heavy loams behave and should be treated like clay soils. Light loams should be treated like sandy soils. Medium loams are potentially the ideal mixture, exhibiting the advantages of both heavy and light soils without many of the disadvantages of either.

## HUMUS

This is a stable form of partially decomposed plant material that gives topsoil its characteristically dark colour. Humus has a high nutrient-reserve potential (2½ x better than clay), retains water, increases the friability (suitability for cultivation) of heavy soils and its darker colour encourages soils to warm up more rapidly.

### SOIL PROFILE

*A typical soil profile usually consists of three main elements: an upper layer of dark, fertile topsoil; a middle layer of lighter, infertile subsoil; and a lower layer of bedrock, which ranges from a few to hundreds of metres (yards) deep.*



### MANAGING YOUR SOIL

Any soil has the potential to be a fertile growing medium in which plants will thrive if it is managed correctly.

**Management of light/sandy soils**

- Maintain levels of organic matter.
- Lime when required. (N.B. It is often easier to select species tolerant of the site conditions in the long term.)
- Fertilize well as light soils are usually infertile. (N.B. Some exotic and native plant species actually thrive under relatively poor nutrient conditions.)
- Irrigate frequently in the first year after planting, less so once deeper roots are established.

**Management of clay soils**

- Drainage is essential.
- Maintain lime status.
- Maintain levels of organic matter and fertilize when needed.
- Wise cultivation is needed to conserve winter or summer tilth produced by natural weathering, i.e. cracking due to wetting/drying cycle and breakdown by frost action.

# SOIL STRUCTURE

*Soils are made up of mineral and rock particles that give them their natural properties. The character of the mineral fraction cannot be changed but the way that these building blocks are organized within the soil can. Creating and maintaining soil structure is a key aspect of maintaining the fertility of the soil and supporting healthy plant growth. Even the most difficult soils can be modified to create a fertile growing medium for plants.*

Above: *Even "difficult" soils can be transformed into a good growing medium by careful cultivation.*

## WHAT IS MEANT BY SOIL STRUCTURE?

Soil structure is quite simply the way soils are organized. To use a simple analogy: if we see the soil particles (sand, silt or clay – the mineral fraction) as the building materials – like the bricks and mortar of a house, for instance – then the structure is the architecture. The building materials themselves cannot be altered, but the architecture can vary considerably from home to home. This is the key. It is possible to improve a soil's structure even if the mineral fraction remains unchanged. It is perfectly feasible to have a well-structured clay soil for instance. It all depends upon how well you manage it.

## WHY IS SOIL STRUCTURE IMPORTANT FOR PLANT GROWTH?

In order to survive, plant roots need water, nutrients and air. Plant roots breathe in the soil, taking in oxygen and expelling carbon dioxide. A poorly structured soil may have too little airspace. This can have two negative effects. Fresh air (containing oxygen) may not be able to penetrate the soil very easily and the soil will tend to become waterlogged following rain. Waterlogging will also reduce the air available in the soil.

Below: *A rotavator is a useful and labour-reducing method of breaking up the soil to prepare it for planting.*

Structure is therefore very important in terms of maintaining the health of plant roots. Plant shoot development is directly linked to root health. A healthy root system ensures healthy shoots and will ultimately result in better growth and crop yields.

## HOW DOES SOIL STRUCTURE DEVELOP IN NATURAL SYSTEMS?

Soil structure naturally develops in soils through the effect of weather cycles. Wetting causes soils to swell while drying causes shrinkage. This naturally causes soils to crack. The action of freezing and thawing is also important on clay soils in areas where frosts occur. They form particles known commonly as crumbs. The "crumb structure" of any soil develops over time and is important in terms of allowing the free passage of water through the soil and air that must be able to move in and out of the soil. In this way soils do not become habitually waterlogged and natural nutrient cycles – oxygen, carbon and nitrogen, for example – are not impeded. Plant roots and soil organisms, such as worms, naturally help to maintain soil structure, as does the natural addition of decaying plant material each autumn.

## HOW TO ALTER SOIL STRUCTURE

Humans have learned over time that even an infertile area can be worked – and the structure of the soil improved – by cultivation. This is covered in more detail later but it is essential to understand now that cultivation is a way of rapidly accelerating the natural cycles that promote good structure. Digging and breaking down "clods" helps to introduce air and creates new pores in the soil. Adding organic matter helps to maintain these pore spaces, retains moisture (in dry soils) and encourages the action of soil-dwelling creatures such as worms. No-dig

Above: *If you need to work on wet soil, work from a plank of wood to ensure the soil is not compacted and its structure destroyed.*

systems aim to harness this natural cycle more closely, but the goal is the same – a rich, fertile and well-structured soil.

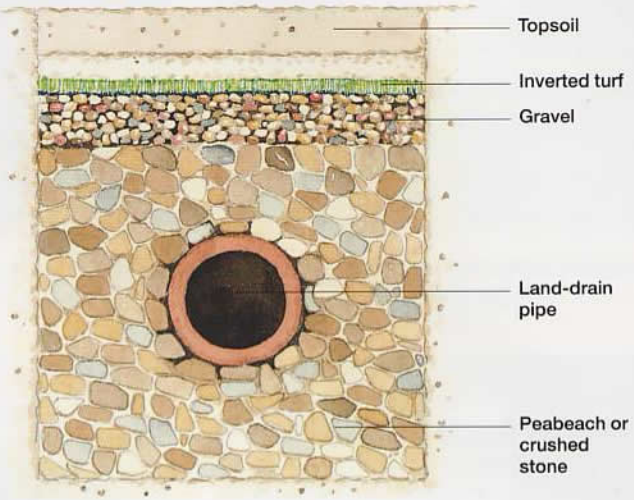
## IMPROVING DRAINAGE

Soils that tend to become waterlogged often do so as a result of poor structure and because there is nowhere for the water to go. The vast majority of soils do not actually need (or benefit from) the installation of land drains. Often it is enough to dig over a site because much of the drainage problem may be due to surface compaction. Surface compaction severely reduces the passage of water into the soil and can result in a sticky surface that is prone to "puddling". Installing land drains is usually only done where the water table is very near to the surface or the consequences of flooding are severe (if they threaten housing or use of the area for instance). Land drainage using pipes or "tiles" is a complex undertaking and may be best left to a contractor.

If you have a sloping site you can dig a "soak away" drain at the base of the slope and improve the structure of the soil to encourage the rapid dispersal of water following rain. If you have a fairly flat site, then you should consider making a raised bed for growing crops. Raised beds are easy to manage and avoid the inconvenience of installing (and maintaining) a drainage system.

### SECTION THROUGH A LAND DRAIN

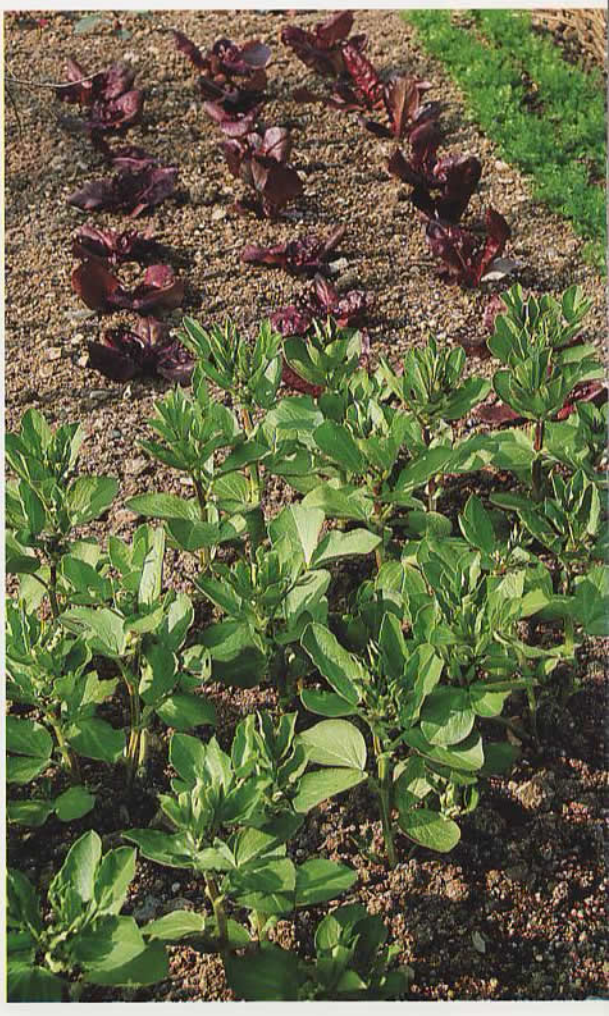
*This cross-section of a typical land drain shows the various layers of materials from which it is constructed, including the topsoil, an inverted turf or perforated plastic membrane, gravel, peabeach or crushed stone, and the land-drain pipe.*



## IMPROVING SOIL STRUCTURE

**1** *One of the best ways to improve the structure of the soil is to add as much organic material as you can, preferably when the soil is dug. For heavy soils, this is best done in the autumn.*

**2** *If the soil has already been dug, then well-rotted organic material can be worked into the surface of the soil with a fork. The worms will complete the task of working it into the soil.*



Above: *A well-prepared soil that is kept free of weeds and dug regularly will result in healthier, more vigorous crops throughout the growing season. A healthier crop will be more resistant to pest and disease attack.*

# SOIL CHEMISTRY

*While for many of us the word chemistry can be extremely off-putting, the truth of the matter is that everything in life is made up of chemicals. While the pure science of chemistry can be very complex, the chemistry of soil that organic gardeners must master is mercifully simple. A rudimentary knowledge of the chemicals that affect plant growth and how soil chemistry can be controlled and managed is all you need to grow healthy plants in an organic garden.*

Above: *You can reduce the acidity of the soil by adding lime some weeks before planting. Test the soil first to see how much is needed.*

## OXYGEN

The amount of oxygen in a healthy soil controls the type of life it will support. Nearly all organisms need oxygen to survive. Soils without oxygen are described as anaerobic. Most organisms can survive for short periods under anaerobic conditions, but this causes the accumulation of poisons that can become toxic at high concentrations.

A typical soil has about 50 per cent of its pore space filled by air and 50 per cent by water. Only certain bacteria can remain in anaerobic conditions for long periods of time, although some species of bacteria can readily switch from oxygen-rich to oxygen-poor conditions quickly to adapt to local conditions. Microbes use about 70 per cent of the oxygen in the soil and plant roots use the remaining 30 per cent. Under anaerobic conditions, the efficiency of microbes is poor and decomposition rates are much slower.

## WATER

Soil water is vital for all soil life. Without it, microbes cannot grow or remain active and many will go into "hibernation" until water returns. Fungi, on the other hand, are more resistant to water stress than bacteria. With too much water, oxygen levels drop and the lack of air tends to slow down the nutrient cycles driven by microbes. Water is also the medium by which essential nutrients are able to enter the plant.

## SOIL pH

The pH scale is an abbreviated form of "Potential of Hydrogen". It is a measure of the degree of acidity or the alkalinity of a solution as measured on a scale (pH scale) of 0 to 14. The midpoint of 7.0 on the pH scale represents neutrality. A "neutral" solution is, therefore, neither acid nor alkaline. Numbers below 7.0 indicate acidity; numbers greater than 7.0 indicate alkalinity.

The level of acidity or alkalinity (pH) of a soil can significantly affect the nutrient availability. Many nutrients become "unavailable" to plants when the soil is either too acid or too alkaline. Microbial activity in soil is also largely controlled by pH. Fungi tend to predominate in acid soils, bacteria in neutral or alkaline soils.

Soil pH is essentially a measure of the acidity of the soil water, although the soil itself is the deciding factor in respect of what this will be.

Most plants prefer or are tolerant of a specific pH range. Some plants, such as the hydrangea, exhibit a different flower colour depending upon the prevailing pH. Most garden plants, especially vegetables, thrive within a range of 6–7 which happens to be where the majority of nutrients are available. It is best to maintain this pH in order to optimize the availability of nutrients. Many garden plants, however, are not too fussy about the pH levels, so if you choose plants carefully, it will not usually be necessary to alter the soil acidity.

## ACIDIFYING SOIL

Lowering the pH of a naturally limy soil is difficult because the soil often contains a reserve of calcium that is released immediately upon acidification. Lowering the pH involves the use of flowers of sulphur and is only usually successful over a short period of time.

## TAKING A pH TEST

**1** *Place the soil in a test tube until it reaches the mark on the side. For the most accurate results, dry the sample first, grind it into a powder and ensure it is free from stones.*

**2** *Put a layer of barium sulphate powder into the tube level with the mark. This compound helps the solution to clear rapidly and makes the pH reading clearer.*

**3** *Pour in a little of the indicator solution up to the mark shown on the tube. Be careful not to put in too much because this can make the solution dark and difficult to read.*

## MAKING A NUTRIENT TEST

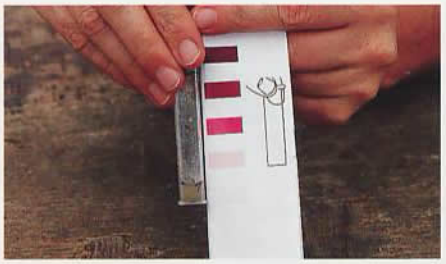
**1** *Place a small sample of the soil into the test tube up to the mark on the side.*

**2** *Add a test solution (in this case one for nitrogen) up to the mark on the test tube.*

**3** *Filter the solution to remove soil particles and leave just a liquid solution.*

**4** *Decant the resulting filtered solution into another container for the final stage of the nutrient test.*

**5** *Add a small amount of indicator powder. This will react with the solution and enable a colour reading to be taken.*



**6** *Shake for about 10 seconds and compare with the chart. Here, the low reading indicates that a nitrogen-rich fertilizer will benefit this soil.*

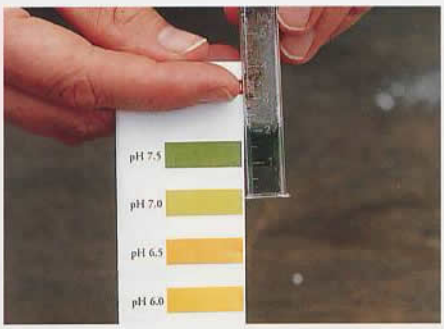
### LIMING SOIL

It is generally easier to raise the soil pH than to lower it. Lime neutralizes soil acidity and is commonly applied as ground limestone, chalk or dolomitic limestone (dolodust). Lime requirement cannot be determined from soil pH because it is influenced by soil texture and organic matter content. Clay and humus act as a "buffer" because of their complex chemistry. If soil is known to be acidic, regular light application is preferable to heavier, more infrequent, doses.

### HIGHLY ALKALINE SOILS

Soils that are too alkaline suffer trace element deficiencies of manganese, copper, iron, zinc and boron. Phosphates are also less available, their maximum availability being between pH 6–7. Disease organisms can be more of a problem in calcium-rich soils, as many disease-causing fungal agents prefer alkaline conditions. Some plants, such as rhododendrons, are intolerant of high pH and only grow on acid soils, while others, like helianthemums, thrive in highly alkaline soils.

**4** *Add distilled water to the mark on the tube and shake the container vigorously for about a minute. Ensure the contents are mixed thoroughly and leave to settle.*



**5** *Once sufficiently cleared, compare the colour against those on the chart, choosing the one that most closely matches that of the solution.*

### GROWTH RESTRICTIONS IN EXTREMES OF PH

Many vital nutrients that are essential for healthy plant growth become unavailable in extremes of soil pH.

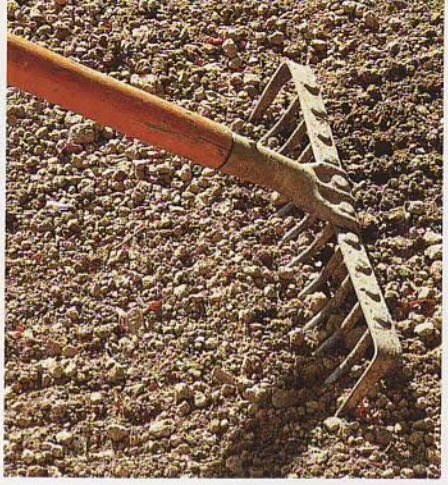
**Nitrogen deficiency** Most nitrates are released from organic matter and a low soil pH limits the rate of decomposition severely.

**Phosphate deficiency** Phosphate becomes unavailable outside the 6.5–7.5 pH range. Some plants form relationships with soil-borne fungi that release phosphates in acid conditions.

**Trace-element toxicity and deficiency** Trace elements, especially aluminium, iron and manganese, are generally more soluble in acidic conditions. Extreme acidity can lead to excessive quantities of trace elements and to plant death. Other trace elements, such as copper, boron and molybdenum, become less available at low soil pH. Molybdenum deficiency affects legumes, which will not grow in acid soils.

# DIGGING AND CULTIVATION

*Every organic gardener's goal should be a healthy soil to support plant growth and development. Digging is one of the commonest ways to create a rich, fertile and ultimately productive soil. It can be hard work at the outset, particularly on sites not cultivated for some time, but the results – in the form of healthier, more productive plants – are worth it. Quite simply, what you get out of your soil will depend upon what you put into it.*



Above: *After a winter exposed to the weather, most soils can be easily broken into a fine tilth with a rake.*

## THE BENEFITS OF DIGGING

Winter is the commonest time to dig, but soil can be dug at any time of the year if the conditions are right. Avoid working the soil when it is too dry and impenetrable, or too wet and sticking to your tools and boots. Clay soils may be best dug in mid- to late autumn to allow the action of frost to make the soil more suitable for final cultivation. Lighter soils are best dug in the spring or immediately prior to planting the site. Done properly, digging increases the amount of air space in the soil, which in turn benefits soil-dwelling organisms and plant roots due to the increase in oxygen available. It also lets you add organic matter that will feed these vital denizens of the soil and aid nutrient cycling. Calculate how much organic matter you will need before you start. You should aim to add about 30 per cent of the volume cultivated. A 20m$^2$ (220ft$^2$) plot cultivated to one spade's depth will need 2.5 cubic metres (88 cubic feet) of manure or garden compost.

## SINGLE DIGGING

This method involves digging down to the depth of one spade (this is called a spit). Single digging suffices on light free-draining soil as long as there is no layer of compacted stones in the topsoil. Much of the procedure is the same as for double digging, but the subsoil is left undisturbed. Mark out the position of the bed. Remove any turf or vegetation from the surface, put to one side and then bury it in the bottom of the bed as you proceed. Work across the bed, digging out a trench that is two spits wide and a single spit deep, and place the soil to one side. Remove stones and perennial weeds as you go. Fork well-rotted manure or compost into the trench. Begin digging a new trench behind the first. Throw the soil forward into the first trench, burying the organic matter. Repeat this process of trenching down the bed until the last trench has been dug. Add organic matter to the base and fill the trench with the soil dug from the first trench.

## DOUBLE DIGGING

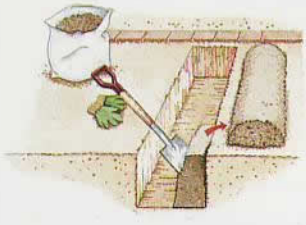
This is a method for deeply digging the soil, in which the soil is broken up to a depth of approximately 70cm (28in) or more. The method usually involves digging a quantity of soil and setting it aside while aerating and sometimes adding an amendment to the subsoil below, then returning the topsoil. There are several methods of double digging, all of which have their advocates. Two methods for double digging are described here.

First, define the area where the digging will take place, making an estimate of the area to be dug. Dig a trench, 30cm (12in) wide and a spit deep, across half the width of the bed. Place the excavated soil next to the other half, placing it on to a tarpaulin or similar covering if the surface needs protection.

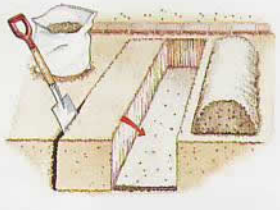
When the trench is complete, fork the subsoil, rocking it back and forth, to loosen it down to a depth of about 30cm (12in). Then, spread a layer of garden compost over

### SINGLE DIGGING

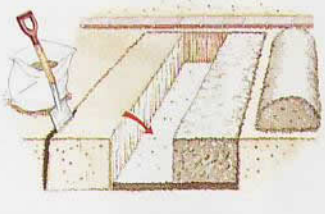
*Single digging is the simplest method of cultivation. It is well suited to light soils or those soils that have been well worked for a number of years. It simply involves digging and inverting the soil to a single spade's depth, leaving the subsoil below undisturbed.*



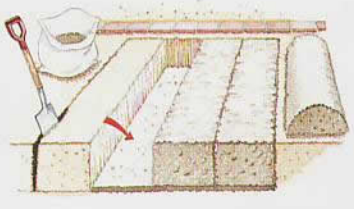
**1** *Start by digging a single trench across the width of the plot. Put the soil from the first trench to one side because you will need to use it later in the final trench.*



**2** *Put a layer of manure in the bottom of the trench. Dig out the next trench and cover over the manure in the first trench with the earth taken from the second trench.*



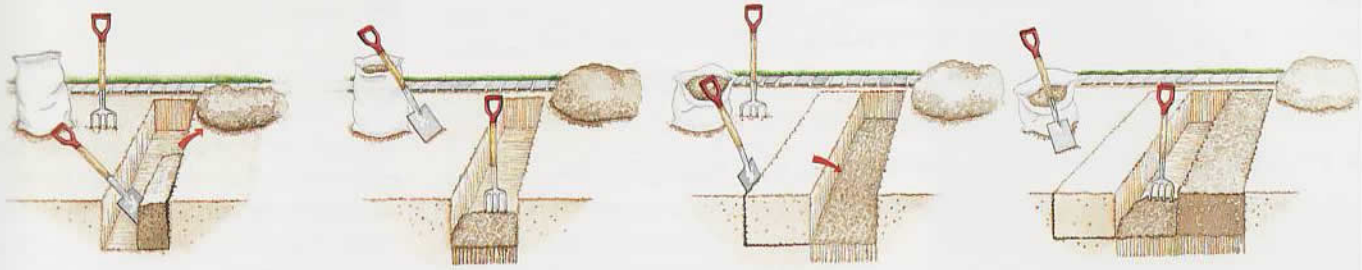
**3** *Repeat this process of adding manure to each trench and filling in with earth from the next, breaking up the soil as you go and keeping the surface as even as possible.*



**4** *Continue down the length of the plot until you reach the final trench. This should be filled in with the earth taken from the first trench, which was set to one side.*

### DOUBLE DIGGING, METHOD ONE

*Double digging is a good method for compacted, heavy or poor soils that are in need of rejuvenation. It involves a deep cultivation of both the topsoil and subsoil and is well worth the hard work, producing a wonderful soil in which plants will thrive.*



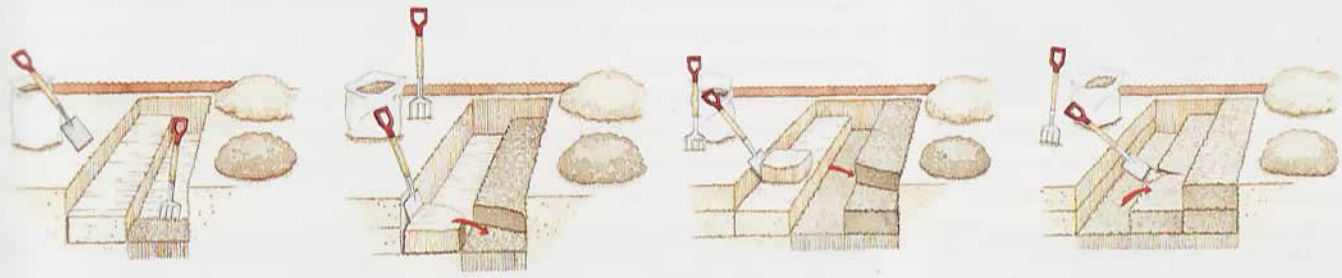
**1** *Dig a wide trench, placing the soil to one side to be used later when filling in the final trench.*

**2** *Break up the soil at the bottom of the trench with a fork, adding manure to the soil as you proceed.*

**3** *Dig the next trench in the bed, turning the soil over on top of the broken soil in the first trench.*

**4** *Continue down the plot, ensuring that subsoil from the lower trench is not mixed with topsoil of the upper.*

### DOUBLE DIGGING, METHOD TWO



**1** *Keeping soil from each level separate, dig the first trench two spits deep and fork over. Dig the second trench one spit deep.*

**2** *Add organic material to the first double trench and dig the lower spit of the second trench into it.*

**3** *Dig an upper third trench one spit deep, and place the soil on top of that already placed in the first trench.*

**4** *Continue, ensuring that the topsoil and subsoil do not mix. Fill in remaining trenches with soil taken from the first one.*

the exposed subsoil. Move over one spit's width in the bed, and begin to dig out another trench, moving and inverting the excavated soil into the adjacent trench that was just dug. When you get to the end of the bed replace the soil which was set aside.

When the digging is finished, level the site prior to planting. More garden compost (approximately 8cm/3in) can be spread over the surface and forked in at this stage.

You do not have to dig the entire garden all at once. Instead, work on small areas, say, one metre (yard) square, whenever you wish. Once you double-dig a bed, it is important not to walk on it. After all, the whole point of double digging is to loosen the topsoil and the subsoil to a sufficient depth so that the roots of the plants can grow unrestricted and water can readily percolate through the soil. Walking on the soil will simply pack it down again.

There is a second method of double digging that is less commonly used, which enriches the soil to a greater depth.

### SECONDARY CULTIVATION

This normally involves the nourishing of the soil after it has been cultivated by digging and usually entails the addition of some form of organic matter during, or immediately after, its completion. Secondary cultivation also describes light digging used to control weeds or incorporate green manures. The tool generally used for this is a fork. Light forking is often the best method to use in areas with permanent plantings of perennial plants or shrubs.

### USING A ROTAVATOR

A rotavator is a useful labour-saving device for breaking down dug clods and creating a fine, free-running "tilth" that can easily be levelled for planting or seed-bed preparation.

### TIPS FOR DIGGING

Digging can be hard work, but simply following the tips given below will help you to avoid strains and injuries.

- Start with a small area, pace yourself and avoid straining your back.
- Use a spade that is right for you and the job. It should be a little higher than hip height when held vertically.
- Do not try to lift more than you can handle. You will dig for longer periods of time by taking smaller amounts.
- As you work, try to establish a rhythm that you can maintain at all times.
- When doing a lot of heavy digging, scrape the blade clean now and then, and, if necessary, use a file to sharpen the end of the spade, following the original bevel of the blade.

# NO-DIG GARDENING

*As the name suggests, no-dig gardening is a method of growing plants without cultivating the ground they occupy. While this may seem unnatural to some confirmed tillers of the soil, it is actually the most natural method available. No-dig gardening mimics the natural cycle. After all, plants have grown on the earth's surface for over 400 million years without people digging the soil for them. This approach also has the advantage of being less labour-intensive.*

Above: *In nature, organic matter accumulates on the soil surface, breaks down and is worked into the soil by worms.*

## ESTABLISHING A NATURAL CYCLE

Essentially no-dig gardening relies upon natural soil processes combined with the action of soil organisms to produce a good soil structure and natural nutrient cycles. There are numerous ways that this can be done, but all rely upon inputs from the top down. A thick top-dressing of organic matter is placed on the surface to be absorbed by the soil itself. Less laborious than digging, the no-dig method does need planning and careful input in order to be successful, although a properly prepared no-dig bed will be every bit as effective as a conventionally cultivated one.

Left: *Many organic gardeners grow crops such as potatoes quite successfully without ever resorting to digging.*

## WHAT ARE THE BENEFITS?

Assuming weeds can be controlled, most vegetable crops can be grown with reduced tillage. The key features of a no-dig vegetable-growing system are to keep the soil covered with organic mulch as much of the time as possible and to keep off the soil. The beds are left permanently in place, and there is no cultivation.

Plants grown without tillage use water more efficiently, the water-holding capacity of the soil increases, and water loss from run-off and evaporation are reduced. For crops grown without irrigation in drought-prone soils, this more efficient use of water can translate into higher yields.

In addition, the organic matter in soil and populations of beneficial insects are maintained, as are earthworm populations and microbial activity. Soil and nutrients are less likely to be lost from the ground, less time is required to prepare the soil for planting, and, since there is less bare soil, there will be fewer opportunities for weeds to get established. The mulch of organic matter also helps to keep weeds down.

## WHAT ARE THE DISADVANTAGES?

Potential problems associated with the no-dig method are compaction, flooding and poor drainage. However, if the water-holding capacity of a soil improves, no-till systems may produce higher yields. Soil temperatures under organic mulch can be several degrees lower than bare soil or soil under a plastic mulch. Although the lower temperature can be an advantage, especially in the summer when soil temperatures under plastic can be excessive, it can delay crop development.

### WHAT ARE THE BENEFITS OF NO-DIG SYSTEMS TO THE ORGANIC GARDENER?

Although no-dig beds may require a little longer to establish initially than cultivated plots, they do offer considerable labour-saving advantages to the organic gardener. They also suffer very few disadvantages when these are weighed against the considerable advantages.

**Advantages**

- Plants use water more efficiently.
- Better water-holding capacity of the soil.
- Reduced water loss from run-off and evaporation.
- Higher crop yields in areas prone to drought.
- Organic matter in the soil and soil organisms are maintained at higher levels.
- The lower temperature can be an advantage, especially in summer when soil temperatures under plastic can be excessive.
- Soil and nutrients are more easily maintained.
- Less time is required to prepare the soil for planting.
- Fewer weeds become established due to the mulch of organic matter and the lack of bare soil.

**Disadvantages**

- Soil can become compacted or poorly drained if it is not properly managed.
- Soil temperatures under an organic mulch can be several degrees lower than bare soil, which can delay the development of crops.

## MAKING A NO-DIG BED

A bed system which includes permanent paths is essential if digging is to be eliminated from gardening tasks. Planning the area so that all parts of the bed can be reached from the paths means that you can grow your crops closer together (you do not need to leave extra space for access) and you will be able to harvest more from a smaller area.

Mark out the beds on the ground or build simple raised beds with wooden sides. Alternatively, those wishing to make a more permanent edge could consider a low brick wall. By raising the bed it is possible to create a deep bed of good-quality soil that will warm up more quickly than the surrounding soil. A raised bed also means you do not have to bend down so far to carry out routine tasks and the method is tailor-made for disabled gardeners. Raised edging is also useful for attaching supporting hoops, crop covers and cloches. Edges such as these are also ideal for providing barriers for pests. Devices such as water traps or copper paper are easily attached to them to prevent slugs and snails from entering the bed.

Beds should be no more than 1.2m (4ft) wide and paths at least 30cm (12in) wide with every other path double this width to allow for easy wheelbarrow access. Individual beds should be no longer than 3.5m (12ft) otherwise you will waste a lot of time walking around them. The beds can be of any design, from a simple series of parallel rectangles to a more complex design of interlocking shapes. Whatever design you choose, try to follow the same recommended bed and path widths, remembering that narrow angles and very small beds are more difficult to construct and use space less efficiently.

Right: *Green manures are usually dug into the soil, but they can still be used in a no-dig system. The manure can be cut down and left as a mulch.*

## PLANTING POTATOES IN A NO-DIG BED

**1** *Place a thick layer of well-rotted manure or garden compost on the bed to be planted. This should be quite deep – at least 15–20cm (6–8in) – as it will quickly decompose during the growing season. Early planting is possible by manuring in winter and covering with plastic sheeting to warm the soil. The potatoes are planted directly into this and may be more closely spaced than those planted in soil, perhaps as close as 30cm (12in) apart.*

**2** *Apply a generous mulch of straw once the bed is planted to give cover to the tubers and to suppress weed growth on the manure or compost. Spread a second layer of composted organic material over the straw. Add another layer of straw and composted material. Water the bed well. Once the potato plants begin to emerge, more straw can be laid down on to the bed, as the material put down earlier in the season will begin to compost down.*

**3** *As the potato stems grow, mulch heavily in order to ensure that no light reaches the developing tubers. The potato crop will mature at the same rate as potatoes grown in ordinary soil. The no-dig system is possibly the best method for heavy clay soils that are prone to waterlogging. Potatoes grown in this way are also easy to harvest as there is no digging and the potatoes are cleaner once they are ready for harvesting.*

# SOIL CONDITIONERS

*There is quite a range of conditioners available to the organic gardener for improving the soil. Some are free (if you do not count the time taken in working and carting them), others are relatively cheap, while those bought by the bag can be quite expensive. The best option for the organic gardener begins with using the materials that are closest to hand. Smaller gardens or those that are newly established may require soil conditioners to be brought in. This section looks at some of the options.*

Above: *A well-conditioned soil will pay dividends in terms of enhanced plant growth and development.*

## FARMYARD MANURE

This is usually freely available, although these days it comes increasingly from stables rather than farms. It contains a small amount of nutrients although it usually makes the soil more acidic as it decomposes and should always be well rotted before use. It can also contain lots of weed seeds, which often come from the bedding used for the animals. Occasionally there can be problems if the straw used has been sprayed with pesticides, so always be sure of your source. Farmyard manure is usually cheap or occasionally free for the taking.

## BURYING GREEN WASTE

If you have space, you can simply open a trench in the soil and bury your green waste 20–30cm (8–12in) deep under the soil. It will take perhaps two to three months during the warm season to break down. Avoid planting crops in the soil above until the material has decomposed properly.

Left: *Animal manures can provide both nutrients and valuable organic matter when added to your garden soil.*

Left: *Spent mushroom compost is an ideal material for improving the structure of many types of soil.*

## LEAF MOULD

Many gardeners believe leaf mould to be the finest addition to any soil. The product itself forms naturally under the closed canopy of forest trees. It is, as the name suggests, the rotted product of fallen leaves. It is not particularly rich in nutrients but it has an extremely good ability to condition a soil and encourages natural nutrient cycles in your soil. It is usually made by the gardeners that wish to use it and is rarely sold on. Anyone who has a ready supply of leaves will find this an easy material to make.

Start by gathering up leaves in the autumn and stack in a chicken-wire cage to prevent them being blown back over the garden. Do not add any greens or other materials to the pile. The heap will rot down slowly and be ready for use in one to two years. It can be sited in a dark corner where nothing else will grow, but you must ensure that you keep the pile moist all year round. The wire cage can be removed after two months or so and used again the following autumn. Alternatively, two permanent pits, sited side by side, can be filled (or emptied) in alternate years. Smaller quantities of leaves can be pushed into black plastic sacks with the top closed and with holes pierced by a garden fork around the sides and bottom of the bag to allow some airflow.

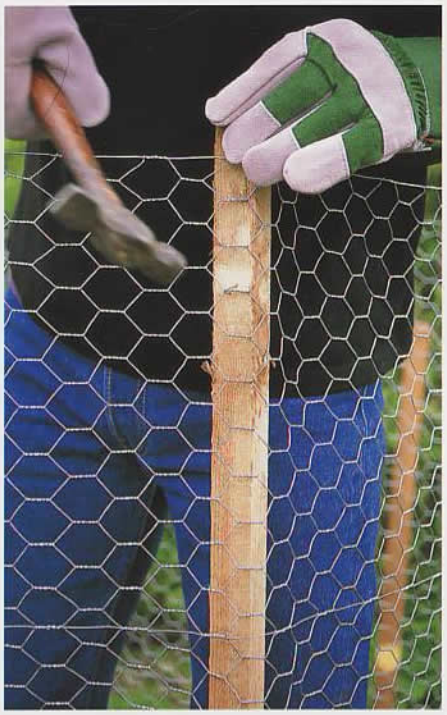
## SPENT MUSHROOM COMPOST

This is one of the few types of organic matter to have a slightly alkaline effect on the soil. It is a uniform and friable mixture of stable organic materials that is a waste product of the mushroom-growing industry. It is usually quite inexpensive. The composting and growing processes that produce this material bind nutrients to the organic matter, resulting in a substance that holds on to nutrients more readily than fresh or non-composted organic wastes. In addition, the compost has good moisture-holding abilities.

Spent mushroom compost is slightly alkaline with a pH ranging from 7–8 but generally around 7.3. There are few weed seeds, insects or pathogens because the compost is pasteurized before it is removed from the mushroom house. The addition of spent compost to garden soil can result in a

## BUILDING A LEAF MOULD PIT

**1** *Drive in four 1.5m (5ft) posts to form the four corners of a square on the ground. The posts should be spaced about 1m (3ft) apart and there should be just over 1m left above ground once the posts are driven in.*



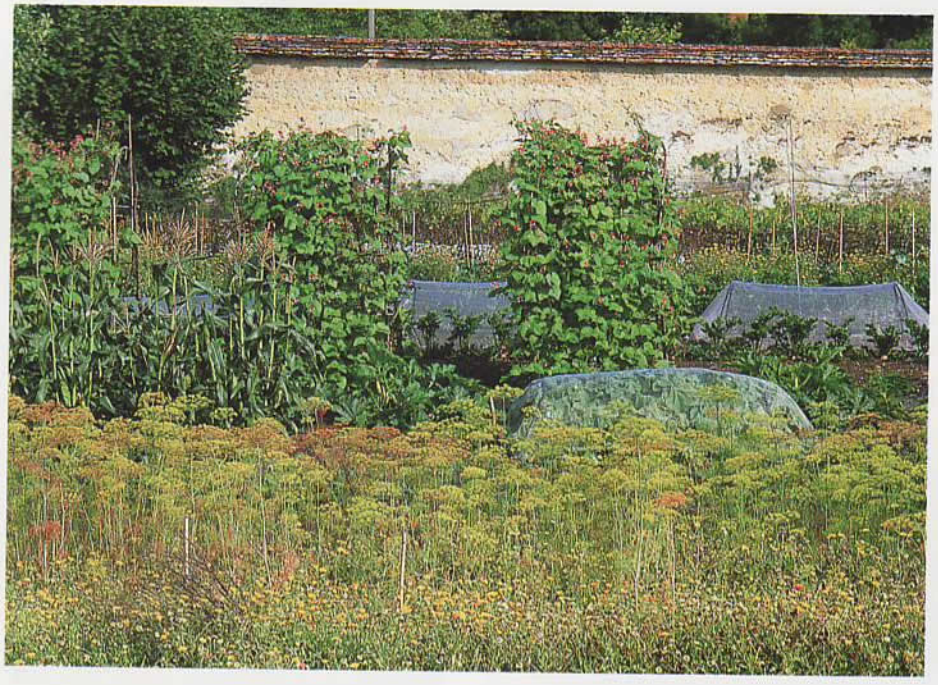
**2** *Attach chicken wire – a 1m (3ft) wide roll is needed for this – to the stakes using "U"-shaped fencing staples, hammered in firmly. Pull the wire tight across the length of the roll before attaching it to the next post.*

**3** *Once the wire has been securely stapled to the posts all the way around, cut it with wire cutters, folding the sharp ends under the attached mesh so that they cannot cut you.*

**4** *Place fallen leaves into the "pit" until it is full. Firm the leaves lightly in layers as you go, so that the pit is completely packed with leaves but still contains a little air.*

**5** *After a year or two, the leaf mould is ready and should be applied to the soil in late winter or early spring in order to gain the most benefit.*

**6** *It is a good idea to build two or more pits and rotate their use as a single pit will not be emptied in time to receive the new lot of leaves in the following autumn.*



Left: *Beans and other leguminous plants are an important part of a successful organic vegetable garden, "fixing" their own nitrogen and so helping to raise levels of soil fertility.*

higher pH, increased nutrient-holding capacity and better soil structure. The main disadvantage occurs when the compost is first mixed with soil, as bacteria convert the proteins in the compost to ammonia, which can be toxic to young plants. Always ensure the source of your compost is an organic mushroom grower where possible.

### VEGETABLE INDUSTRIAL WASTE

Some by-products of the food industry, such as spent hop waste and cocoa shells, can be beneficial as soil conditioners in the organic garden. They are useful in terms of their ability to improve soil structure. However, their smell, which may be described as rancid ale or beer with hops, or sickly cocoa, is often enough to put people off. They are sometimes marketed commercially although they may be available as a local by-product of industry. Whatever product you use, it should be well rotted before it is used as a soil conditioner.

### WORM COMPOST

Worms can be used to compost your kitchen waste both indoors and outdoors, although both methods have their limitations and advantages.

The materials that are being composted are consumed by the worms and then excreted as worm casts. This process binds the nutrients consumed into a form that can be used by plants and reduces the volume of the original materials. These worm casts are covered with slow-dissolving, semi-permeable mucus that acts as a time-release mechanism for the nutritional content of the worm casts and also gives the finished compost good water-retentive qualities.

Above: *Brandling or tiger worms readily reduce vegetable matter into a useful compost material within a wormery.*

### A WORMERY

*Worms are an effective way to break down kitchen waste such as vegetable scraps. They will eventually eat their bedding as well as the kitchen waste. The resulting worm casts are a nutrient-rich soil conditioner.*

Worm colonies can be built in a similar way to a cold pile compost heap, with materials added as they become available. Excessive heat and frequent pile turning are not needed. Too much heat will actually kill the worms. Alternatively, a purpose-built wormery can be used. Both methods require materials to be placed in a shaded, cool and moist location. The worm colony must not become heated by the microbial action that takes place in normal composting. If the colony does get hot, it may cause the loss of the worms if they do not have cooler areas to which they can escape.

For an indoor worm colony, the wormery (a sealed, ventilated box with a close-fitting lid) is filled with bedding materials (usually damp shredded newspaper or similar) and the worms are added. Vegetable waste from the kitchen is placed on top or a few inches under the bedding where the worms can find and devour it. Eventually, the worms eat their bedding as well as the vegetable scraps. The finished worm castings can be removed and used. New bedding and kitchen scraps are then placed in the container and the worms returned to make a new batch of compost. Many purchased wormeries have the facility to collect the liquid by-product of the worms' activities, which makes an excellent liquid plant food.

It is advisable to check the pH level of the wormery every now and then. Thin, white, thread-like cotton worms are usually an indication that the pH is too low. Adding some calcified seaweed can help to counter this acidity, as can a regular addition of eggshells.

Above: *Place a thick layer – about 8–10cm (4–5in) – of well-rotted organic matter into the base of a trench dug to a spit's depth (the depth of a spade blade). Use a fork to break up the material and to ensure that there is plenty of air space in the soil to aid the breakdown of the material and help soil organisms to cycle the nutrients.*

Above: *Leafy crops benefit from the addition of organic matter because it encourages nitrogen-fixing bacteria to do their all-important work in the soil.*

**THE BENEFITS OF ADDING ORGANIC MATTER**

Using organic matter as a mulch or soil conditioner will help to warm up the soil earlier in the spring. This in turn will allow for the earlier planting of some types of plant.

- Organic matter inoculates the soil with vast numbers of beneficial microbes and provides the food source that soil-dwelling microbes need to live. These microbes are able to extract nutrients from the mineral part of the soil and eventually pass the nutrients on to plants.
- Adding organic matter to your soil improves the way in which water interacts with the soil and improves the overall soil structure. All soils can benefit from the regular addition of organic matter.

**To sandy soils**

- Organic matter acts as a sponge to help retain water that would otherwise drain down below the reach of plant roots. This has the benefit of protecting plants against drought.

**To clay soils**

- Organic matter helps to increase the air space within the soil, making it drain more quickly. This ensures that the soil does not become waterlogged or dry out into a brick-like substance.

# MAKING GARDEN COMPOST

*Every organic garden should have at least one compost heap, where garden and kitchen waste can be broken down by microbes and other soil-dwelling creatures to produce a good medium-fertility soil improver. Making compost is not difficult and is an excellent way to recycle waste. Many gardeners take great pride in their home-produced compost and all gardens can benefit from this sustainable approach to soil improvement.*

Above: *Even a stack of old tyres can be recycled and used to make an effective compost heap.*

## THE SITE

A position in full sun will give the compost heap additional heat, allowing the contents to decompose more rapidly. If time is not a key factor, partial shade or even full shade will do. Compost is easily made in a freestanding pile in a sunny or partially shaded area in the garden. Alternatively, a simple structure can be used to contain the pile. A variety of materials can be used to make these structures, including wood, bricks, pallets, a wire cage or even a stack of used tyres. Whichever method you use, you must provide good drainage. An average heap should be around a cubic metre (10 cu. ft). It can be much larger, but any smaller and it will not be as effective.

When adding waste materials to the heap, the items should be as small as you can make them. The more surface area that is exposed, the quicker it will decompose. A chipper or shredder is a big help. Many gardeners are keen advocates of adding a small amount of good topsoil in order to introduce microorganisms that will kick-start the process of decomposition. Compost heaps in containers can be built up with successive layers of "green" and "brown" materials, separating these with thin layers of topsoil.

Sifting the pile is the final stage of the process, with any large pieces of residue being returned back to the new heap.

Left: *Composting your garden and kitchen waste ensures that you return essential nutrients to the soil.*

## COMPOST INGREDIENTS

The potential ingredients for your compost heap will be either "brown" or "green". Browns are dry and dead plant materials, such as straw, hay, dry brown weeds, autumn leaves, nutshells, shredded paper, pine needles, tough plant stems and wood chips or sawdust. Because they tend to be dry, browns often need to be moistened before they are put into a compost system.

Greens are fresh (and often green) plant materials, such as green weeds from the garden, fruit and vegetable scraps, green leaves, grass clippings, tea bags, coffee grounds, seaweed, eggshells, fish scraps, green manures and fresh horse manure. Compared with browns, greens contain

## MAKING A HOT PILE COMPOST HEAP

**1** *Starting with an empty compost bin, place a layer of "browns" – straw, old leaves and chipped wood are ideal – in the base of the bin. If the bin is positioned over bare soil, include some fine twiggy material to help to circulate air to the base of the pile.*

**2** *Add a layer of brown compost materials, such as autumn leaves, plant stems and wood chips, which should be approximately 15cm (6in) deep, and ensure that it is of an even thickness. The material should be lightly firmed in.*

**3** *Add a new layer of "greens" to the compost bin. Most plant material can be used for this, although you should avoid too much fibrous or woody material such as plant stems. Never include weed seeds if possible.*

*Above: It is often advisable to have two or more compost heaps at any one time in order to ensure a steady supply.*

more nitrogen. Nitrogen is a critical element in amino acids and proteins, and can be thought of as a protein source for the billions of multiplying microbes.

A good mix of browns and greens is the best nutritional balance for microbes. This mix also improves the aeration and level of water in the pile.

### THE "COLD PILE" METHOD

Make a pile of "browns", such as autumn leaves, moisten them well and then slowly incorporate "greens" such as kitchen waste or lawn clippings over the next year (this method can take a full year to finish the compost). If it gets very cold in winter, cover the heap with cardboard or old carpet and peel this back to stir in any greens. In this type of composting, there are never enough high-nitrogen greens to get the pile really hot. Turn the pile a minimum of once a month if you have not recently added any greens, thereby breaking up the decaying mass and making it friable. If you do use this method, be sure you always have at least as much browns as added greens, as too many greens will just create a slimy, smelly mess. Some compost heaps (those with lots of greens added) may reach very high temperatures, some even reaching 70°C (158°F), thereby killing weed seeds. Cold piles, on the other hand, do not and it is best not to add any weed wastes that will contain seeds. If you do, you could risk spreading weed seeds across your garden in their own growing mix when you come to use the compost.

### THE "HOT PILE" METHOD

Wet the ground under the pile and add twigs or other un-shredded browns to provide some aeration at the base. Layer the rest of your materials, alternating green and brown layers of about 15cm (6in) thickness, and add water as you go. Topsoil can also be added as a 2cm (¾in) layer between each cycle of green and brown materials. Finish the pile with a layer of browns. Cover the pile with a lid or piece of carpet to keep out rain and conserve heat. Check to see that your pile becomes hot within a few days. Turn the pile to decrease composting time. This action allows all the material to be exposed to the hot centre, thereby increasing aeration. Do this once a week in the warmer season, and once a month in cooler periods. The pile's heat should peak every time you turn it, although the peak temperature will be lower with each turn. Always make sure that the pile remains moist, but avoid over-wetting.

#### COMPOSTING MATERIALS

Many items can be composted into valuable soil conditioners. Whether because of toxins, plant or human diseases or weed problems, some things should never be used.

**Good compost materials**

Animal manure
Fallen leaves
Grass/lawn clippings
Hay and straw from organic farms
Kitchen waste
Prunings from the garden
Sawdust
Shredded browns
Soot and charcoal
Spent hops or cocoa shells
Spent mushroom compost
Weeds and other garden wastes

**What not to compost**

Chemically treated wood products
Diseased plants
Human and pet waste
Meat, bones and fatty food wastes
Pernicious weeds

4 *Continue adding greens until you have a layer about 15cm (6in) thick, the same depth as the browns below. Lawn clippings should be placed in layers of about 10cm (4in) or mixed with other green waste to avoid the layer becoming slimy and airless.*

**5** *Kitchen refuse, such as vegetable waste, can also be added and is usually classed as a "green". You can include a thin layer of soil to add microorganisms before the next layer of "browns". Continue layering until the bin is full, then water and cover.*

**6** *After two to three months, you should have well-rotted garden compost, which, due to the heat of the pile, will be largely free from weed seeds, pests and diseases. Once the bin has been emptied, it can be refilled in the same way.*

# GREEN MANURES

*Sometimes referred to as "cover crops", green manures are plants that are grown to benefit the soil rather than for consumption or display. Green manures replace and hold nutrients, improve the structure of the soil and increase its organic material content. They also smother the soil and so prevent weed growth. Green manures also "fix" atmospheric nitrogen. They are easy to grow and can be used to improve the soil when manures are not readily available.*

Above: *Growing a green manure is an easy and effective way in which to add some organic matter to the soil.*

## BENEFITS OF GREEN MANURES

At any time of year, but especially in winter, the soil loses nutrients if it is bare for six weeks or more. Green manures help to counteract this and maintain a more even soil temperature and moisture content. Many green manures grow deep roots to tap resources unavailable to some crops. Others produce a fibrous root system to help build structure in the soil, while many have flowers that attract pollinating insects.

## TYPES OF GREEN MANURE

Some green manures are nitrogen-fixers, using bacteria that colonize the nodules on their roots. These microbes take nitrogen out of the air and convert it into a form that plants can use. Green manures are usually divided into two groups: legumes and non-legumes. Leguminous manures include clover, peas, fava beans and alfalfa. Despite their nitrogen-fixing abilities, legumes have slow autumn growth and add less organic content. They can also be less winter hardy.

Winter rye is the most commonly grown non-leguminous cover crop, but oats, wheat, oilseed rape and buckwheat are also used. Although they do not add nitrogen to the soil, they help maintain levels and have the additional advantage over legumes of growing faster through the autumn, thereby giving better weed suppression. They also tend to break down more slowly than legumes and add more organic matter to the soil. You may wish to use a combination of green manures in order to balance the benefits of the different types.

## DEEP-ROOTED GREEN MANURES

The roots of certain green manure "crops" work through the soil, holding it together as they grow. Once dug in, however, they help to make it crumbly and friable as they rot. Some green manures have very deep roots that reach down into the subsoil and can harvest nutrients that are unavailable to other garden plants. In this respect they are a form of biological double digging.

## PLANTING GREEN MANURES

Winter green manures should be planted early enough to give about four weeks of growth before cold weather stops their growth. Spring or summer crops must be given sufficient time to develop before they are dug in. After preparing the soil, plant large-seeded cover crops in shallow, closely spaced furrows. Smaller seeds can be broadcast over the surface and covered with a light raking, watering if needed until they germinate. Dig the crop in once it is ready, allowing at least three weeks before you intend to plant to give time for the material to rot down. It is best not to allow green manures to go to seed as they all have the potential to become weeds.

Gardens are traditionally dug over and manured in autumn, then left bare over winter. Many nutrients can be lost during this time due to the leaching action of rain. A hardy green manure sown in the autumn can be dug in the following spring, yielding nutrients to a newly sown or planted crop.

## USING GREEN MANURES

**1** *Sow the seed evenly across the area where you plan to grow the green manure. Either broadcast the seed or sow larger seed thinly in shallow drills and close rows.*

**2** *Lightly rake in the seed so that it is covered and will germinate quickly. Water the area thoroughly if there is no rain due or if it does not rain for the following 48 hours.*

**3** *Once the seed germinates, allow it to grow a little before digging it into the soil. Never let green manure crops set seed or they will become a weed in later crops on the site.*

## TYPES OF GREEN MANURE

### Green manure for growing over winter

These species can withstand moderate to hard frost for a long period and can be cut down in the spring, prior to cultivation. The shorter types can also be used as catch (cover) crops around winter vegetables or biennial crops for harvest in the early spring. This protects bare soil, prevents nutrient leaching and creates a more stable soil environment.

| GREEN MANURE | SOWING TIME AND METHOD | HEIGHT | WINTER HARDY? | NITROGEN-FIXING ABILITY | TERMS OF GROWTH | DIGGING IN | OTHER NOTES |
|---|---|---|---|---|---|---|---|
| **Alfalfa** *Medicago sativa* | Early spring to mid-summer; broadcast at 3g (1/10oz) per square metre (yard). | 100–150cm (3–5ft) | Yes | Yes but poor | Perennial. Grow for several months or more than one season. | Any time. Medium effort if young. Hard if left for more than one season. | Very deep rooting. Will grow on most soils. Dislikes acid or waterlogged soils, but drought resistant. |
| **Asilke clover** *Trifolium hybridum* | Mid-spring to late summer; broadcast at 3g (1/10oz) per square metre (yard). | 30cm (12in) | Yes | Yes | Several months | Any time. Medium effort. | Will withstand wetter soils than other clovers but more prone to drought. Shallow rooted. |
| **Essex or red merviot clover** *Trifolium pratense* | Mid-spring to late summer; broadcast at 3g (1/10oz) per square metre (yard). | 40cm (16in) | Yes | Yes | Several months | Any time. Easy, little effort. | Prefers good loamy soil. Can be mown or cut several times per season and used for compost. |
| **Grazing rye** *Secale cereale* | Late summer to late autumn; broadcast at 30g (1oz) per square metre (yard) or thinly in rows 20cm (8in) apart. | 30–60cm (12–24in) | Yes | No | Autumn to spring | Before flowering. Hard work. | Grows in most soils. Keep watered during germination, else yield is poor. Sow thickly to smother weeds. |
| **Phacelia** *Phacelia tanacetifolium* | Early spring to early autumn; broadcast at 3g (1/10oz) per square metre (yard) or thinly in rows 20cm (8in) apart. | 60–90cm (12–36in) | Yes | No | 2 months in summer; 5–6 months over winter | Before flowering. Easy, little effort. | Grows in most soils. Quick to grow in summer. If left, will produce mauve flowers that bees love. |
| **Trefoil** *Medicago lupulina* | Early spring to late summer; broadcast at 3g (1/10oz) per square metre (yard). | 30–60cm (12–24in) | Yes | Yes | Several months to a year | Any time. Medium effort. | Will grow in most soils but dislikes acid. Can be used for undersowing. Dense foliage. |

### Green manure for warm-season growing

Plants for use in the spring and summer have to be quick growing in order to cover the ground and yield benefit within a short period of time. They are generally slightly tender, although lower-growing species can actually be used as a catch crop around other seasonal crops.

| GREEN MANURE | SOWING TIME AND METHOD | HEIGHT | WINTER HARDY? | NITROGEN-FIXING ABILITY | TERMS OF GROWTH | DIGGING IN | OTHER NOTES |
|---|---|---|---|---|---|---|---|
| **Bitter lupin** *Lupinus angustifolius* | Early spring to early summer 4cm (1½in) deep; 3cm (1¼in) apart; in rows 15cm (6in) apart. | 50cm (20in) | Mild winters | Yes | 2–3 months | Before flowering. Easy, little effort. | Prefers light slightly acidic soil. Foliage not very dense. Deep rooted. |
| **Buckwheat** *Fagopyrum esculentum* | Early spring to late summer; broadcast at 10g (1/3oz) per square metre (yard) or thinly in shallow rows 20cm (8in) apart. | 80cm (32in) | No | No | 2–3 months | Before or during flowering. Easy, no effort. | Grows on poor soils. If allowed to flower, attracts hoverflies to aid pollination of crops. |
| **Crimson clover** *Trifolium incarnatum* | Early spring to late summer; broadcast at 3g (1/10oz) per square metre (yard). | 30–60cm (12–24in) | Mild winters only | Yes | 2–3 months or over winter | Before flowering. Medium effort. | Prefers sandy loam soil but will tolerate heavy clay. Large red flowers attract bees. |
| **Fenugreek** *Trigonella foenum-graecum* | Early spring to late summer; broadcast at 5g (1/5oz) per square metre (yard) or thinly in 15cm (6in) shallow rows. | 30–60cm (12–24in) | Mild winters | No | 2–3 months | Any time before flowering. Easy, little effort. | Prefers good drainage but will tolerate heavy or light soil. |

# BASIC TECHNIQUES

Most gardening techniques, from weeding and feeding to pruning and propagation, are straightforward and and easy to achieve if you plan and organize the task in hand. The procedures described here will help you to master the basics of organic gardening. You may well develop your own methods in time, based upon the techniques shown here as well as those you that learn from other gardeners. Always make sure that you are clear what you want to do and always approach a task positively. Gardening should bring enjoyment as well as a sense of satisfaction that comes from creating a thriving organic paradise in your own backyard.

Left: *A flourishing garden plot is the end result of careful planning and preparation as well as regular maintenance.*

Above: *A well-prepared, weed-free plot is the ideal starting point for successful plant growth and development.*

Above: *Both weeds and crop residues can be recycled in the organic garden by composting and then returned to the soil.*

Above: *Taller plants may need some form of support. In this case, willow branches have been used to support* Lysimachia.

# WEEDING AND WEED CONTROL

*Many people are put off organic gardening because they do not like the idea of weeding. Not having the "quick fix" of weed-killing chemicals can make this task seem daunting. It is, however, worth considering that a well-maintained garden has less weeding to do than you might think. In addition, it can be a relaxing, even therapeutic, task and there is very little that is more satisfying in the garden than a freshly weeded plot.*

Above: *Hoeing is an effective way of keeping a garden plot free of weeds. Pull a draw or swan-neck hoe towards you in a series of chopping movements.*

### WHAT PROBLEMS DO WEEDS PRESENT?

Weeds compete with garden plants of all types for essential nutrients, light and water. Uncontrolled weed growth may kill plants that are less vigorous or seriously inhibit their development. Weeds also act as "host" plants for animal pests or diseases that may, in turn, affect the desired plants. Finally, weeds are controlled because they often look unsightly.

### CAN WEEDS BE TOLERATED?

There is no easy answer to this question. It depends upon what exactly you want out of your garden. Aesthetic considerations aside, most gardens can survive quite healthily with some weeds. The majority only become a real nuisance when they start to take over or if they set seed. The simple rule is the fewer weeds in the garden the better.

Left: *Weed-free plots can be attractive to crop pests. Here, plant collars have been used to prevent root flies attacking the crop.*

### GOOD CULTIVATION

The secret of organic weed control is good cultivation. This begins with thorough ground preparation to reduce the build-up of weeds and weed seeds before planting. Fallowing is commonly used to do this. After the ground has been prepared, it is left bare for a period of a few weeks to a few months. The weed seeds are allowed to germinate and are then removed as they appear. This method will never remove all the seeds because they can survive for several years in a dormant state. But the majority of them will have germinated and the task of weed control made easier for the future.

Vigilance is important throughout the growing season, but never more so than in spring and early summer. Tackle weed seedlings as they appear. Some methods of control, such as hoeing, may damage garden plants, so use a hand fork for close work or in areas where hoeing is difficult. A hoe, for example, can sever the roots of surface-rooting shrubs such as rhododendrons. These weeding methods are relatively slow and labour-intensive. The trick is to do it little and often.

Flails, brush cutters, mowers, rollers, burning and other mechanical means are occasionally used. Although strimmers can be used in shrub borders, those that cut using nylon cords can damage woody stems.

### MINIMAL CULTIVATION

Many weeds are plants of cultivation, thriving in disturbed ground. Minimal cultivation reduces disturbance and relies on creating a ground-covering layer of vegetation. The plants literally out-compete the weeds, which can be removed as they appear.

### COMMON WEEDS

Weeds can be divided into three groups. Annual weeds germinate, grow, flower and set seed in one growing season. Certain annuals, which are known as ephemerals, complete their lifecycle well within this period and can produce several successive generations within the space of one season. The third type of weeds are perennial species. Perennial weeds initially establish from seed, but tend to persist for several seasons, sometimes dying down during adverse seasons only to re-emerge as conditions improve. They are much more difficult to eradicate once established than annual weeds and many are a serious problem in gardens.

**Ephemeral and annual weeds**

- Annual meadow grass
- Bittercress
- Chickweed

**Perennial weeds**

- Blackberry (in Australia)
- Couch grass
- Creeping buttercup
- Dock
- Ground elder
- Groundsel
- Nettle

Meadow grass

Chickweed

Creeping buttercup

Dandelion

### DIFFERENT TYPES OF MULCH

Mulches provide a physical barrier to weed seeds that would otherwise land on the soil surface. The materials that can be used for mulching are varied in their composition and the effects they have. They are generally classified into synthetic and natural types.

Bark chippings

Newspaper

Dried bracken

Gravel

Old carpet

Sawdust

Woven plastic

Cocoa shells

### MULCH

This is a layer of material that is laid over the surface of a soil or other growing medium. While often cited as a means of weed control, applying mulch has other functions that are beneficial to growth. Mulches help to keep the plants' roots warm in winter and cool in summer, greatly assisting new growth in the spring. They also reduce water loss from the soil in two main ways: by shading the soil surface and by slowing down evaporation of water from the soil.

In general, most mulches reduce the number of weeds growing in a planted area. They act by inhibiting the germinating weed seedling from reaching the sunlight or by "drawing up" the weed so that it is spindly and can be easily removed or "pulled". Mulches should be laid on a bare surface, as they will not inhibit established weeds, especially vigorous perennial ones.

If a mulch is laid to an even depth of around 5cm (2in), it will develop a dry dusty surface that will deter the germination of weed seeds that land on it. This is only a temporary measure, but can help reduce weeding at the busiest times of the year.

### TIMING AND APPLICATION

Mulches should be laid on warm, moist soil. Autumn is the ideal time, but they can be applied in the spring after the soil has warmed up. Applied too thickly (over 10cm/4in), they may affect water infiltration into the soil. Materials containing an excessive amount of fine humus or soil-like material ("fines") may encourage weed seedlings to establish. In poor-draining soil, mulch may keep the soil waterlogged and this will be detrimental to plant growth. Synthetic materials, especially if they are impermeable such as black plastic, will inhibit oxygen and water infiltration into the soil. Some materials, such as grass clippings, can "pack down" on the surface and form a water-shedding layer.

As mulches encourage surface-rooting, application must be continued once started, otherwise the plants will suffer later. Many ornamental plants, such as rhododendrons, are naturally very shallow-rooting and thus need the protection of mulch for good growth. They benefit from an organic mulch that conserves soil moisture. Some mulches, such as manure and compost, also aid plant development by supplying nutrients.

### MULCHING TO CONTROL WEEDS

**1** *Grass clippings are a cheap, effective mulch. Apply them at a maximum depth of 5cm (2in) or the heat they create as they decompose may harm the stems. Do not use mowings from grass that has gone to seed.*

**2** *Chipped bark should be composted or stored for several months to let it release any resin and start to decompose. Some gardeners worry that it introduces fungal diseases, but the spores are already in the air.*

# WATERING

*In order to cultivate a successful organic garden, it is crucial to recognize the water requirements of different plants. It is of vital importance that you know when and how to provide the right amount of water as well as how to avoid either drought or waterlogging. Conserving the water in the soil as well as storing and recycling this valuable commodity are of key importance in the organic garden, especially in areas where rainfall is seasonal and droughts are common.*

Above: *Water that runs off the roof can be collected in a custom-made rainwater butt, and stored for later use.*

## PRINCIPLES OF WATER MANAGEMENT

After rainfall or irrigation, all the soil pore spaces are filled with water. The air is displaced and the soil saturated. If the rain or irrigation were to continue, then surface pooling or runoff would occur. The rate at which a soil can absorb water is influenced by its texture and structure.

Water drains from the soil through the pore system and is replaced to some extent by air. After draining has removed the excess water, the remaining water may be lost either through evaporation or taken up by the plant and lost through its leaves.

All sands and loamy sands tend to have a low available water capacity. Loams and clay have a medium capacity while very fine sandy loam, silt loams, peats and any soil with a high water table have high available water capacity. Clay soils often have a large amount of water within them, but it is held so tightly that plants are not able to obtain it.

## WATER AND THE PLANT

All plants are largely made of water and it is critical that water levels are maintained if the plant is to grow and develop. Soft fleshy subjects, such as many bedding plants and some vegetables, use large quantities of water, particularly during establishment. Plants with large leaves or with extensive branch systems, such as large trees, will remove gallons of water from the soil in the course of a hot sunny day.

## WATERWISE GARDENING

Since water supplies are limited, we need to do all we can to conserve soil moisture. As the top layer of soil dries out, the dry soil acts as an insulation to further rapid moisture loss. Take advantage of this by avoiding over-cultivation, particularly during the summer, as this may bring moist soil to the surface to dry out. Always try to maintain a well-structured soil and avoid capping (a hard, partially compacted surface layer) as this can prevent the absorption of rainfall by the soil, leaving puddles that quickly evaporate. Mulches help to conserve moisture either by holding water or acting as insulation provided that they are deep enough. Keep the soil surface weed-free and provide shelter from drying winds. Maintain drainage, as poor drainage leads to limited root growth of the plant and poor soil structure.

## STORING AND RECYCLING WATER

Water is a precious resource that is sometimes in short supply. Plants in open ground may acclimatize to the soil conditions, but those growing in pots are more susceptible to drought. Mains water can provide an answer but there is a cost involved and supplies can be restricted. Saving water from rainfall or recycling waste water (which is sometimes called "grey water") can overcome the worst ravages of summer drought.

## METHODS OF WATERING

**1** *When watering by hand, be patient and give the ground around the plant a good soaking. If in doubt, dig a small hole in the soil and check that the water has soaked through to the roots.*

**2** *Turning on a sprinkler allows you to leave it and get on with something else. Place a jar under the spray to gauge how much has fallen. There should be at least 2.5cm (1in) of water for the sprinkler to have done any good.*

**3** *A spray attached to a garden hose delivers at a greater rate than a sprinkler but it must be held in place until the ground is soaked. It is easy to under-water using this method. Spray the leaves to wash away dirt or dust.*

**4** *A seep hose with holes in it is snaked around plants that need to be watered and left in position. When connected, it provides a gradual but steady flow of water that penetrates deeply into the soil.*

## AUTOMATIC WATERING SYSTEMS

1 *You can bury a pipeline beneath the surface and plug in various watering devices. A sprinkler can be pushed on to this fitting, which lies flush with the turf.*

2 *Control systems can be fitted to the hose system so that you can alter the pressure of the water. These can also act as a filter.*

3 *Drip-feed systems can be used for beds, borders and containers. "T"-joints allow tubes to be attached for individual drip heads.*

4 *The delivery tube of the garden hose can be held firmly in position with a pipe peg that is inserted into the ground, if this is necessary.*

Storing and recycling household water is a relatively complicated undertaking that is usually best left to specialist contractors. The potential health risks mean that it is not usually wise to store this type of water for any length of time, but it can be used fresh to water non-food plants. Try keeping your bath water and using it to water ornamental plants. It can be used to fill watering cans and is ideal for watering outdoor pot specimens or plants in open ground.

Rainwater may be a viable alternative and some contractors will be able to install large underground tanks to contain seasonal rainfall. The quicker and easier alternative is to install water butts to collect water from downspouts from roof drains. This method will rarely provide enough water for your whole garden, but is often plenty to water (or supplement the watering of) plants in containers, particularly edible plants such as herbs. Rainwater is naturally acidic and is, therefore, not likely to contain many harmful bacteria. Its acidity also makes it the ideal choice for misting plants under glass on hot days (as it will not mark the leaves with lime) and suits many species sensitive to domestic water additives. Rainwater is also a must for people wishing to grow "acid-loving" specimens in pots.

### WATERING PLANTS

In areas where seasonal water shortage is a regular problem, choose drought-tolerant species where possible. Seasonal crops (such as vegetables) and displays (summer or spring bedding) tend to suffer the most from drought due to the limited time that they have to develop extensive root systems. If you wish to grow these seasonal plants in drier areas, they will need to be watered regularly to survive prolonged dry periods. Perennials, on the other hand, may actually become more drought-tolerant if they are watered less. This is because they will have to root deeper to find water. Perennials will need to be watered in their first season following planting to ensure their long-term survival. Remember that applying a good drench on a more occasional basis allows the water to penetrate more deeply and have a better long-term effect because it encourages deeper rooting. Watering little and often can prove detrimental in drier climates by encouraging surface roots that may become very drought-prone. After the first growing season following planting, they are better able to cope if not watered at all.

### WATERING METHODS

Plants can be watered in many ways, but all generally fall into two categories: hand watering or automatic systems.

**Hand watering** The commonest "tool" here is the watering can. Numerous designs exist but they all rely upon a gradual delivery through a spout. A rose ensures that a fine spray is delivered that will not wash away soil or damage plants. Hoses can also be used for hand-watering and many nozzles have been designed to deliver a shower of water rather than a jet.

**Automated systems** There is an array of devices to choose from, some of which can deliver doses of water at set times of the day or week. Even the most complex of these use relatively simple water-delivery methods such as seep or drip hoses and sprinklers. Seep and drip hoses are essentially "leaky pipes" that gradually release water into the soil. Sprinklers shower an area of garden repeatedly until the ground is well soaked. There are many designs for both and the amount of time they need to be left on depends upon the manufacturer's recommendations and the available water pressure. Both hoses and sprinklers offer the benefit of gradual delivery over a large area and both can be operated manually from a mains water supply. A good watering every few days can be extremely beneficial to most plants, especially if recently planted.

### WATERING PROBLEMS

These are usually the result of either too much or too little water being applied to the plant. Both over- and under-watering have similar symptoms because both are related to root death. An over-watered plant's root system begins to die off due to a lack of oxygen. The plant becomes short of water and wilts. Other problems can result from the wetting of foliage and flowers. Watering in full sunlight can give plants a scorched appearance, so it is best not to water in hot sunny conditions.

#### RECYCLING WATER

The suitability of the water left over from washing, bathing and other household activities depends on how much waste matter it contains. Ordinary bath water, for instance, is useful for watering a variety of plants, but the main problem lies in its storage. Waste water always carries the risk of bacterial infestation. Specialist storage methods and filtration can be used, but it is easier to use it immediately (once cooled), and to avoid using it on houseplants or edible crops.

# FEEDING

*In order for plants to grow and sustain their life processes, they require water and air as well as a range of naturally occurring elements. At least sixteen different elements are needed by all plants for successful growth and development. Three of these elements – carbon, hydrogen and oxygen – are obtained from the carbon dioxide in the air and from the water and oxygen in the soil. In addition to these, plants also need a selection of other important nutrients, which are described here.*

Above: *Top-dressing with organic matter provides the soil with nutrients and encourages nutrient cycles.*

## IMPORTANT PLANT NUTRIENTS

In addition to carbon, hydrogen and oxygen, plants need other important nutrients, which they obtain directly from the soil or compost. These nutrients are commonly divided into two groups, depending upon whether they are found in plants in high or low concentrations. When they are found in high concentrations and are needed in large amounts, they are known as macro or major nutrients. There are three of these: nitrogen (N), phosphorus (P) and potassium (K). Every organic gardener must be fully aware of the functions of the "essential three". Nitrogen is essentially the shoot and leaf maker and is especially important early in the growing season; phosphorus is important in the formation of roots; and potassium plays a vital role in flower and fruit formation and is also important in promoting hardiness in overwintering plants. Elements that are needed in relatively small amounts are the micro or trace elements, of which there are ten. Among the most important of these are calcium, magnesium and sulphur, although all play a vital role in the growth and development of the plant.

### ORGANIC FERTILIZERS

A wide variety of organic substances can boost nutrient levels. They should be used in addition to composts and manures.

**Animal manure** Bird manure is a good source of nitrogen. Use in pellet form, as the fresh substance will burn plant roots.

Bonemeal

**Bonemeal** Promotes strong root growth due to its high phosphate content. Use it as a base dressing prior to planting perennials.

**Calcified seaweed** This raises the pH of the soil and adds calcium, like limestone, but also contains magnesium.

Fish, blood and bone

**Fish, blood and bone** A general fertilizer that is normally applied in the spring to promote root and shoot growth.

**Ground limestone** This raises the pH and supplies calcium where there is a deficiency. It is applied as a powder when it is needed.

**Gypsum** This supplies calcium to soils where there is a deficiency, but does not alter the pH. It is added in a 4:1 ratio to "lighten" clay soils.

Hoof and horn

**Hoof and horn** This material gives a slow release of nitrogen where strong growth is needed and is applied in the spring or early summer.

**Rock phosphate** Used mostly to counter phosphate deficiency and as an alternative to bonemeal.

**Seaweed meal** Helps to build up humus levels in the soil and is used on a wide range of plants.

Calcified seaweed

**Wood ash** An excellent source of potassium that can be added directly to the soil or to a compost heap.

## SYMPTOMS OF DEFICIENCY

Plants exhibit varying symptoms to a nutrient deficiency. General ones are stunted growth, discoloured leaves, including mottling and inter-veinal coloration, and the premature death of leaves or other parts of the plant. Plants may also display twisted or distorted growth as well as poor root growth and development. In many cases, the symptoms are often seen first in the plant's extremities, such as the tips of the shoots, as these are furthest away from the nutrient source. If a plant cannot obtain enough of any nutrient from a soil it will be because there is either little or no nutrient present in the soil, or the nutrient is not "available" to the plant.

Any element can also be toxic to the plant if it is present in sufficiently high amounts or out of balance with other elements in the growing medium.

## FEEDING PLANTS ORGANICALLY

Numerous organic nutrient supplements are available. All have their relative advantages, but they should be used only as part of a combined strategy that aims to harness natural nutrient cycles. This usually involves top-dressing the soil with well-rotted organic matter. This is the catalyst to nutrient cycling in the soil as it feeds the

## MAKING COMFREY TEA

1 *Cut a large bundle of comfrey leaves from the patch in your garden. Choose good, green, leafy growth. Remove the leaf and stem, but avoid using the crown.*

2 *Place in a plastic container with holes in the base. Weigh down the leaves. Line a second larger container with a plastic bag and place the first container inside. Tie the bag at the top.*

3 *The thick dark liquid from the decomposing comfrey leaves collects in the bag below. The lower bucket allows this to drip down and stores it until the process is complete.*

4 *Decant the finished liquid into a jam jar for later use. The liquid feed must be diluted before it is applied to plants at a ratio of about 10 parts water to 1 part concentrate.*

vast array of soil organisms that naturally make use of essential plant nutrients. The majority of garden composts do not contain especially large amounts of the major plant nutrients; it is their long-term ability to feed soil life that makes them so valuable.

Despite the best intentions, plants can become short of a certain type of nutrient. This is usually avoided by giving the plant a supplement of a "plant food" that is rich in that particular nutrient. This can be applied to the soil as a top-dressing, lightly worked in with a fork, or applied as a foliar feed. Foliar feeding involves spraying a fine mist of a low-strength solution of the feed. The exact concentrations vary according to the feed being used, but a rough guide would be to use a quarter strength of that which you would apply as a liquid feed to the soil. The nutrient will be taken up quickly and the residue is best washed off after a couple of days because any soil-applied fertilizer will have been taken up by then. Applying a weak solution of Epsom salts as a foliar or liquid feed is an example of applying such a tonic.

### LIQUID FEEDS AND TEAS

Compost tea is easy to make. Comfrey is ideal for this, but stinging nettles are also very good. You could also use sheep or goat manure, or finely sifted compost from the heap. Simply fill an old pillowcase or burlap bag with your chosen material (comfrey, nettles, compost or manure) and sink it into a large bucket or barrel of water. Cover the container and let it steep for a few days. Remember, the longer you steep, the stronger the tea will be. You may use the final "brew" as a light liquid feed. It can also be used as a foliar feeding medium, provided that it is well diluted. Use the residue in the bag as mulch. An alternative method is shown above.

Worm colonies in containers also produce a liquid feed that is a tonic for your plants. It should be diluted to a ratio of about 10 parts water to 1 part liquid feed. It is generally high in potassium and phosphorus.

## OTHER FEEDING METHODS

1 *An alternative method of feeding is to use a liquid feed. This is most useful for plants that are growing in containers. Add the organic fertilizer of your choice to one of the waterings, according to the manufacturer's instructions.*

2 *Organic granular fertilizer can be applied by hand, spreading it over the area covered by the roots below. Follow the manufacturer's instructions. You may wish to protect your hands when applying the fertilizer by wearing a pair of gloves.*

3 *Apply a layer of well-rotted organic material, such as farmyard manure or garden compost, to the surface of the soil around the plant. If the plant is not shallow-rooted, lightly fork the material into the top layer of the soil.*

## PLANT NUTRIENTS

The following table highlights the characteristics of the soil nutrients. Symptoms of deficiency may be seen on different parts of the plant at different stages of growth, although it may not always be immediately obvious that a plant is suffering from a nutrient deficiency. Some of the more important symptoms that can be seen on plants are listed below.

| PLANT NUTRIENT | NATURAL ORGANIC SOURCE | PLANTS MOST IN NEED | SOILS MOST IN NEED | SIGNS OF SHORTAGE | HOW TO AVOID SHORTAGE | TOXICITY CAUSE |
|---|---|---|---|---|---|---|
| **Major plant nutrients** | | | | | | |
| **Nitrogen** (N) The "leaf maker" | Bird manure, blood and bone, grass clippings | Grass, vegetables grown for their leaves, and root-bound plants | Sandy soils in rainy areas | Stunted growth; small pale green leaves; weak stems | Apply a base dressing before sowing or planting. Top-dress in spring and summer with organic matter. | Excessive use of nitrogen-rich fertilizer |
| **Phosphates** ($P_2O_5$) The "root maker" | Comfrey, seagrass, horse manure, blood and bone | Young plants, root vegetables, and fruit and seed crops | Sandy soils | Stunted roots and stems; small leaves with a purplish tinge; low fruit yield | Apply a base dressing of bonemeal. Use fish, blood and bone when top-dressing plants. | Excessive use of fertilizer |
| **Potash** ($K_2O$) The "flower and fruit maker" | Comfrey, horse manure, seagrass | Fruit, flowers and potatoes | Sandy soils | Leaf edges turn yellow, then brown; low fruit yield; fruit and flowers poorly coloured | Apply a compound organic fertilizer or wood ash as a base dressing or top-dressing. | Excessive use of fertilizer; lack of magnesium |
| **Minor plant nutrients** | | | | | | |
| **Boron** (B) | Beetroot leaves, horse manure, compost, seagrass, untreated sawdust | Root vegetables, top fruit (apples, pears etc.) | Sandy soils | Brown heart (roots); narrow leaves; corky patches on fruit | Top-dress with compost or apply borax in severe cases. | Irrigation water |
| **Calcium** (Ca) | Dandelion, lucerne hay, comfrey, horse manure, compost, blood and bone | Fruit, flowers, vegetables | Acid and potash-rich soils | Similar to nitrogen shortage – stunted growth and pale green leaves | Apply lime or use gypsum or calcified seaweed. | High pH causes toxicity for some acid-loving plants |
| **Copper** (Cu) | Nettles, yarrow, horse manure, dandelion, chickweed, compost, untreated sawdust | Fruit, vegetables | Sandy soils | Dieback; brown spots on leaves | Top-dress with compost. | Copper-based fungicides |
| **Iron** (Fe) | Stinging nettle, compost, dandelion, horse manure, spinach and seaweed | Rhododendrons, azaleas, camellias | Chalky soils | Yellowing of younger leaves | Trouble can occur on chalky, peaty, very light and acid soils. Iron shortage in chalky soils is due to lock-up by calcium and difficult to avoid. | Rare |
| **Magnesium** (Mg) | Grass clippings, seagrass | Roses, tomatoes | Sandy, peaty and potash-rich soils | Yellow or brown patches between veins of older leaves | Apply a mulch of compost or Epsom salts if deficiency is severe. | None |
| **Manganese** (Mn) | Chickweed, compost, untreated sawdust | Rhododendrons, azaleas, camellias | Chalky soils | Yellowing between the veins of older leaves | Shortage in chalky soils is due to lock-up by calcium (see iron). Acidification for some plants. | None |
| **Molybdenum** (Mo) | Cornstalks, compost, grass clippings | Brassicas | Acid soils | Narrow leaves | Apply lime and top-dress with compost. | None |
| **Sodium** (Na) | Seaweed | Root vegetables, fruit | Sandy soils | Very rare except in a few seaside-loving plants | Not usually warranted. | Land reclaimed from sea |
| **Sulphur** (S) | Cabbage leaves | All plants | Soils in rural areas | Stunted growth and pale green leaves | A light dusting of flowers of sulphur during the year. | Industrial sites and acid rain |
| **Zinc** (Zn) | Horse manure, corn stalks, garden compost, untreated sawdust | Fruit, vegetables | Sandy soils | Dieback | Top-dress with compost. | Leaching from containers |

# BASIC PRUNING

*The task of pruning can seem a daunting prospect to some gardeners, but there is, in fact, no great mystery surrounding pruning and a few basic rules are all you need to get started in most cases. At its simplest level, pruning should be regarded as a way of introducing some order to your garden, giving your plants space to grow and look their best, while also controlling them within a set space. The following section provides some basic advice to enable you to prune with confidence.*

Above: *Regular dead-heading keeps shrubs tidy and promotes further flowering. Cut flowering stems back to a bud or stem division.*

## WHY IS PRUNING NECESSARY?

Pruning is usually carried out to control the growth of stronger subjects that may otherwise damage those of a weaker habit growing alongside; it also ensures plants do not outgrow their allocated space and cause an obstruction. Pruning is also used to train a plant to a specific shape or form; to maintain or improve flowering; and to improve the shape or "balance" of an individual shrub or tree. Finally, it is used to remove dead, damaged, diseased or pest-infected growth. This last type of pruning is referred to as hygienic pruning and helps maintain plant health and vigour.

Constant pruning, however, is not always necessary for the good cultivation of plants. Once a plant has become established and the initial framework has been formed, pruning is often reduced to a minimum. The major exceptions to this include plants that are pruned annually in order to improve flowering, fruiting or quality of foliage. Apples, peaches and other fruit trees and bushes are regularly pruned to increase the yield of fruit. Roses are a good example of an ornamental shrub that benefits from regular pruning, having more vigorous and prolific flowering as a result of cutting back on a yearly basis.

## SUCCESSFUL PRUNING

There are arguably two hallmarks of good pruning: a well-planned, careful and methodical approach to the work undertaken and a good working knowledge of the requirements of the plants that are to be pruned. The real results may not always be apparent for months and, in the case of trees, for years.

With secateurs (hand pruners), always try to place the thin blade on the trunk/branch side of the cut. This will result in a short stub and will also prevent a layer of damaged cambium tissue being left immediately under the line of the cut.

## GOOD AND BAD PRUNING

**1** *A good pruning cut is made just above a strong bud, about 3mm (⅛in) above the bud. It should be a slanting cut, with the higher end above the bud. The bud should generally be outward bound from the plant rather than inward.*

**2** *If the stem has buds or leaves opposite each other, make the cut horizontal, about 3mm (⅛in) above the buds.*

**3** *Always use a sharp pair of secateurs (hand pruners). Blunt ones will produce a ragged or bruised cut, which is likely to introduce disease into the plant.*

**4** *Do not cut too far above a bud. The piece of stem above the bud is likely to die back and the rest of the stem may well die back even further, causing the loss of the whole stem.*

**5** *Do not cut too close to the bud otherwise the bud might be damaged by the secateurs or disease might enter. Too close a cut is likely to cause the stem to die back to the next bud.*

**6** *It is bad practice to slope the cut towards the bud as this makes the stem above the bud too long, which is likely to cause dieback. It also sheds rain on to the bud, which may cause problems.*

## HARD PRUNING SHRUBS

**1** *There are a few shrubs – buddleias are the main and most obvious example – which benefit from being cut hard back each spring. This treatment improves the development of the foliage. Elders* (Sambucus) *and the purple smoke bush* (Cotinus) *should also be treated in this way.* Rosa glauca *also responds very well to this type of hard pruning.*

**2** *Cut the shoots right back almost to the ground. It is important to ensure that you make the cuts just above an outward-facing bud. Cutting back will leave little more than a stump. It may seem a little drastic, but the shrubs will quickly grow again in the spring. If they are not cut back, they become very leggy and do not make such attractive bushes.*

**3** *Several plants that have attractive coloured bark in the winter are best cut to the ground in the spring. So, by the following winter, attractive new shoots will be displayed. The various coloured-stemmed* Rubus, *such as* R. cockburnianus, *as well as some of the dogwoods* (Cornus) *and willow* (Salix), *are good candidates for this treatment.*

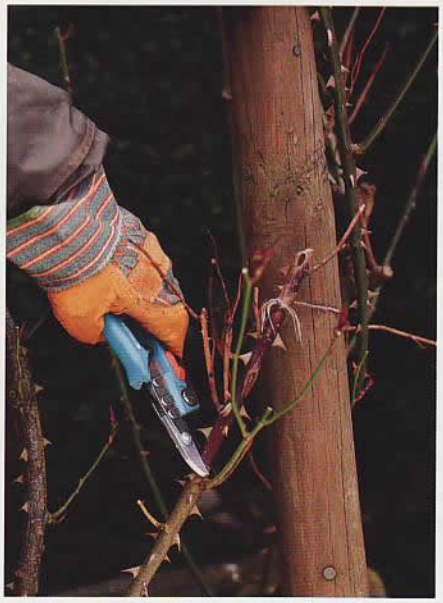
Cuts should always be made immediately above a bud and should be done as cleanly as possible. Use well-maintained secateurs that are regularly sharpened. Make sure that you do not position your blade too close to the bud or the tissue that connects the bud to the main plant body could be damaged. As a guide, you should cut 3mm (⅛in) above a bud and always ensure the bud is not damaged when cutting.

Be careful when using a saw close to a trunk or stem to remove heavier thicker branches. The weight of the branch can sometimes cause splitting and tearing to the main stem wood or bark. These injuries can allow the entry of disease-causing organisms and damage the plant.

The typical order of cuts to follow when pruning any tree is to remember the D's. These are: dead, dying, diseased, displaced or deformed branches. All of these must be removed as the first stage of any pruning work. Then add to this list the C's: criss-crossing branches and crowded growth.

The next stage is to remove any unwanted growth. Care must be applied at this critical stage to ensure that you do not remove too much growth. Finally, once you have cleared this material, it is possible to

Above: *When cutting out crossing stems, cut out the stems while they are still young and free from damage and disease. Using secateurs (hand pruners), cut the stem at its base where it joins the main branch.*



Left: *Tips of stems often die back, especially those that have carried bunches of flowers. Another cause is the young growth at the tip of shoots being killed by frost. If this dieback is not cut out, it can kill off the whole shoot. Even if dieback proceeds no further, the bush looks tidier without these dead shoots. Cut the shoot back into good wood, just above a strong bud.*

## PRUNING OUT DEAD WOOD ON A CLIMBER

1 *Most climbers produce a mass of dead wood that has to be removed so that the plant does not become congested. Dead wood is normally quite clearly differentiated from live wood by its colour and lack of flexibility.*

2 *Thin out all of the dead wood that the climber has produced, removing it very carefully in sections, if this is necessary, so that the remaining stems are not damaged when the dead stems are eventually pulled out.*

see what further work needs to be done. Many species have specific pruning requirements, which need to be carried out if the plant is to reach its full potential. Creating balance, form and a pleasing shape in the pruned specimen requires a keen eye, as well as an understanding of the plant's growth habits and tolerances. It is worth taking a little time over this and planning what you are going to do before starting. Acting too hastily now can easily spoil the job. Pruning is one of a few tasks in the garden that are best viewed intermittently from a distance. Remember, you can only cut a branch once. If you cut the wrong branch, you cannot rejoin it effectively to the plant from whence it came. Always check that you know the full extent of a branch and what effect its removal will have prior to making the cut.

Above: *Up to a third of the old wood should be removed to encourage the climber to produce new growth. If possible, cut some of this out to the base; also remove some of the upper stems, cutting them back to a strong growing point.*

Above: *Remove any wood that has become diseased, cutting it back to a point on the stem where the wood of the climber is healthy. If the cut end shows that the wood is still diseased on the inside of the stem, cut back further still.*

### PRUNING EQUIPMENT

There is a range of tools that can be used for pruning. It is advisable to use the correct tool for a specific task because it will make the process both easier and more efficient.

**Pruning knife** Using a pruning knife requires both skill and a sharp blade. A blunt knife can easily damage the plant. Cut away from you and keep hands clear of the direction of the cut.

**Secateurs (hand pruners)** When small branches are to be removed, it is easiest to use secateurs and remove the branch in one go. Secateurs are the commonest type of pruning tool and are best used on twiggy material up to about the width of a pencil.

**Loppers** Use these on branches up to 2.5cm (1in) thick. Loppers are useful in situations where secateurs may not easily reach, such as in dense tangled shrubs. Loppers should not be used for very thick branches or they may easily be damaged.

**Extension loppers** Ideal for cutting out-of-reach branches up to 2.5cm (1in) thick. They are a useful tool but they can be tiring to use and require some practice.

**Ratchet and snap cut shears** These have three times the power of conventional shears. Used for branches up to 4cm (1½in) in diameter.

**Narrow curved Grecian saw** Use on branches up to 5cm (2in) in diameter where the branches are very crowded. It cuts on a pulling cut, making its use above shoulder height very easy.

**Extension saws** These are similar to Grecian pruning but they have an extended handle. They are very useful where larger branches need removing from smaller garden trees.

**Bow saw** Used for cutting larger branches. Available in various sizes. They cut with a pushing cut, making their use above shoulder height tiring.

# PLANT PROPAGATION

*Despite the large variety of methods employed, there are really only two basic types of plant propagation: vegetative – taking cuttings, for example – and sowing seed. All of the techniques used fall into one or other of these categories. Raising your own plants is one of the most rewarding activities that any gardener can do. It can also be particularly beneficial for the organic gardener because, unlike with bought-in plants, you can be assured that self-raised stock will be pesticide-free.*

Above: *Collecting your own seed can be very rewarding and ensures that your new plants are free of any pesticide residues.*

## POTTING MIX FOR PROPAGATION

Seed and cutting potting mix should be almost free of nutrients – the plants do not need soil-derived nutrients until they have rooted. Numerous proprietary brands are available for organic propagation. Alternatively, you can make your own potting mix using finely sifted compost or leaf mould mixed with equal parts of sharp sand or grit. Mixing this is comparatively easy but problems can arise if the organic matter is not thoroughly sterilized. Unless you are able to do this, there is always the possibility of fungal diseases affecting the plants. Worm compost can be good for making potting mix but the easiest way to get sterilized potting mix is to use compost that was made in a hot pile. Use material from near the middle of the pile to get the most sterilized matter.

## PROPAGATION FROM SEED

Seeds are nature's way of introducing variety into plant material. Fertilizing the female part of a flower with pollen from the male part produces a seed. Seeds are a resting and survival stage in the plant's life that help it survive adverse conditions in nature. Seeds can survive conditions that kill plants. A seed consists of three things: an embryo (a young plant at its most immature stage); a food supply (to maintain the embryo and provide energy after germination); and a protective seed coat. The embryo consists of a young root system (radicle); the young shoot system (plumule), which carries the seed leaves (cotyledons); and the hypocotyl, which is the junction between the root and shoot systems.

Some seeds need special treatment to germinate. One such treatment is stratification. To stratify seeds, cover them in some damp material, such as damp compost, and keep them in a refrigerator at about 4.5°C (40°F) for up to three months. After this treatment, the seeds are ready to germinate. Seeds that germinate better after stratification are oaks and hellebores.

Seeds require moisture, warmth and oxygen to germinate. Because a seed needs oxygen as well as moisture, it is important not to keep the seeds too wet. On the other hand, the seeds must not dry out. Most seeds germinate best between 18.5–24°C (65–75°F). Most seeds will germinate well in light; however, some seeds, such as those of periwinkle, pansy and verbena, germinate best in the dark.

Many seeds have specific germination requirements that require knowledge of the particular species. Certain generalizations are possible and although it is always advisable to follow the instructions on packets you buy, self-collected seed may require a bit of guesswork. If it is a small dust-like seed (thyme and basil, for example), it probably needs light to germinate. Make sure the seed is well pressed into the moist mixture, but do not cover. Larger seed should be covered to twice its thickness in the soilless mixture. If the seed packet says to scarify, make a scar in the seed by nicking the seed coat in some way. Lightly rubbing the seeds with sandpaper usually accomplishes this. The reason for scarification is to speed up the lengthy process of letting the water past the waterproof seed coat.

## MAKING ORGANIC PROPAGATION POTTING MIX

**1** *Take equal quantities of an organic material, such as coir or finely sieved leaf mould, and a free-draining material such as vermiculite or perlite.*

**2** *Mix the organic material and vermiculite or perlite together thoroughly, ensuring that there are no lumps and that the mixture is open and "free running".*

**3** *This organic potting mix for propagation is now ready for use and does not need any additional fertilizer. It can be used to propagate seeds and cuttings.*

## SOWING SEEDS IN CONTAINERS

**1** *First gather together the basic equipment. You will need pots, potting mix, labels, a pencil, a firming board and a plastic bag.*

**2** *Fill the container with the potting mix, gently tapping the pot to ensure that there are no air spaces in the mix.*

**3** *Gently firm and flatten the potting mix with the firming board. Take care not to over-firm the potting mix.*

**4** *Sow the seed evenly over the potting mix surface. Large seed can be placed, but smaller seed must be scattered.*

**5** *With larger seed, lightly cover the seed with finely sieved potting mix. Sieved vermiculite or perlite can also be used.*

**6** *Water the pot using a fine rose on a watering can. If the seed is small, water the potting mix prior to sowing.*

### VEGETATIVE PROPAGATION

The vegetative parts of the plant (stem, root or leaf) can also be used to produce a new plant. Most fruit trees are propagated asexually, using a bud or a twig from a tree that produces exceptionally good fruit. When this bud or twig becomes an adult tree, it has the same qualities as the "mother" tree. By propagating asexually (cloning), we reproduce the "mother" plant.

### PROPAGATING PLANTS FROM SPECIALIZED ORGANS

Plants may be propagated from many different plant parts. Specialized roots, stems and leaves that occur naturally make asexual propagation easy.

**Bulb** This consists of swollen leaves on a short stem. Bulbs can be propagated by removing small bulblets or offsets that form at the base of the parent bulb. These small bulbs take two or three years to mature into plants that flower. Place offsets in rich light soil. Certain bulbs, such as lilies, can be propagated by removing individual scales from the dormant bulb and placing them in a bag of damp moss. After a few months the scale will develop into a small bulb (a bulbil), which can be potted as if it were a large seed and grown on. Certain lilies (tiger lilies, for instance) produce bulbils in their leaf axils (where the bulb leaf joins the stem) that can also be propagated. Examples of bulbs are tulips, onions and lilies.

**Corm** This is similar to a bulb and often confused with one. Structurally, however, a corm is different, consisting of a stem that is swollen as a food store. It is shorter and broader than a bulb. The leaves of the stem are modified as thin dry membranes that enclose the corm and protect it against injury and drying. Examples of corms are crocus and gladiolus. The procedure for propagating these is the same as for taking offsets from bulbs.

**Rhizome** This is a stem that grows horizontally near the soil surface. A rhizome usually stores food, but, as it grows, it develops buds along its length. Rhizomes can be cut into sections with at least one eye or bud. Plants propagated in this way include iris.

**Runner** This is a stem that arises from a crown bud and creeps over the ground. The plantlet that forms at the tip is easily rooted and forms a new plant. Plants with runners include strawberries and spider plants.

**Tuber** This is a swollen underground stem or root that stores food. Tuberous plants, such as potatoes and dahlias, can be dug up and the tubers separated. Each section must have a segment of the crown that contains at least one eye or bud.

## PROPAGATING TUBERS

**1** *Take a sharp knife and cut the tuber (in this case a begonia tuber) through the middle so that each part has a shoot.*

**2** *Dust the open cuts with a fungicide such as sulphur or Bordeaux mixture. Prepare two small pots with moist potting mix.*

**3** *Plant both halves so that they sit firmly on top of the potting mix. Keep the potting mix moist and plant on when new growth appears.*

### ROOT CUTTINGS

To produce a new plant from a root cutting, there must be a shoot bud present or it must be possible for the cutting to form one. The ability of root cuttings to form these buds depends on the time of year. The dormant (resting) season is usually the best time to take root cuttings and it is best to take them from newer root growth.

Make cuttings 3–10cm (1¼–4in) long from roots that are 1–1.5cm (⅜–½in) in diameter. Ensure the roots are from the chosen plant and not neighbouring plants. Cuttings are best taken during the winter, when roots have large carbohydrate supplies, but they may also be taken throughout the growing season. Cut straight through the end of the root closest to the stem. Cut the other end on a slant. This will help you to remember which end is the top (the straight cut) and which is the bottom (the diagonal cut).

Store cuttings from dormant roots for three weeks in moist rooting medium at 5°C (41°F). After this, remove from storage and plant upright in the growing medium. Keep moist and warm in a bright location until the plant has grown large enough to pot on or plant out. This will, of course, vary depending upon the vigour of the plant and slow-growing plants may be best potted up and grown on for a season before finally planting out the following spring.

If root cuttings are taken during active growth, miss out the period of storage and place the cuttings directly in the rooting medium. Phlox and euphorbias are propagated from root cuttings.

### STEM CUTTINGS AND LAYERING

Many trees, shrubs and herbaceous plants are propagated from stem cuttings. A root system must be formed on a stem either before or after the stem is removed. Roots can be formed on stems in two ways: by layering and by taking stem cuttings. With layering, the stem is allowed to produce roots before it is cut from the parent plant.

Stem cuttings form roots after the stem is removed. The main difficulty with stem cuttings is keeping the stems alive while they form new roots. Some plant stems root better when the wood is soft and actively growing, others root best from mature wood. Cuttings taken from plants that are actively growing are called softwood cuttings, while those taken after the wood is mature are known as hardwood cuttings.

## TAKING ROOT CUTTINGS

**1** *Dig up a small section of root from a suitable species with thick fleshy roots. The section must either have a shoot bud or be capable of forming one – in which case the cutting should be taken in the dormant season – if it is to be successful.*

**2** *Remove as much of the soil as possible from the root cutting before slicing off the small side roots. Using a sharp knife, remove these as well as dead and damaged portions and any side shoots to leave a section of healthy root.*

**3** *Cut the remaining sections of the root into small pieces, approximately 5cm (2in) in length, cutting the bottom end at an angle. Insert the root cutting into propagation potting mix, with the angled end pointing down.*

## TAKING HARDWOOD CUTTINGS

1 Select healthy, blemish-free pieces of wood about the thickness of a pencil. Cut each of these into sections about 20–25cm (8–10in) long, angling the top cut.

**2** Stand the cut stems in a jar of water until you are ready to plant them out. Ideally, stand the jar in a cool moist place out of direct sunlight.

**3** Dig a narrow trench that is deep enough for the cuttings. About 2.5–5cm (1–2in) should emerge above ground. The length of the row will depend on the number of cuttings.

4 Loosely fill the trench to about two-thirds full with sharp sand or fine grit. This is essential as it will allow the passage of air around the bases and prevent rotting off. It will also encourage rooting.

**5** Insert the cuttings about 10–15cm (4–6in) apart, making sure that the angled cut is uppermost. If you place any cuttings in upside down – i.e. with the buds facing downward – rooting will not occur.

**6** Gently firm the soil, making sure that the cuttings are firm but that the soil surface is not over-compacted. Leave the cuttings for the whole of the growing season before lifting and planting out next winter.

## TAKING STEM TIP CUTTINGS

1 Take cuttings from the tips of the stems and put them in a plastic bag. The length of the cuttings will vary, depending on the subject, but take about 10cm (4in).

**2** Trim the cuttings to just below a leaf joint and then remove most of the leaves and side shoots, leaving just two at the top. This will help to prevent stem rot.

**3** Place up to twelve cuttings in a pot of potting mix that is specially formulated for cuttings or a 50:50 mixture of sharp sand and peat substitute such as coir or leaf mould mix.

**4** Water well, and cover with the cut-off base of a soft-drinks bottle, a perfect substitute for a propagator. A heated propagator will speed up the rooting process. Place several pots in the same unit.

**Layering** is a useful way of increasing some shrubs and climbers that cannot readily be propagated from cuttings. Simple layering is a method of getting a growing shoot to produce roots while it is still attached to the "parent" plant. There are several variations on the technique, and the one you use will depend on the plant and the type of growth it produces.

**Softwood cuttings** are taken from first-year branches that have not yet become woody. Flowering shrubs are often propagated by softwood cuttings. Late spring and early summer are the best times for success with this method. Take cuttings 5–10cm (2–4in) long. Larger cuttings produce larger plants sooner, but they are prone to more rapid water loss. Make cuts slightly below a leaf node. Remove any leaves on the lower section and insert them into potting mix, making sure that no leaves are touching each other or the potting mix. Remove any cuttings immediately from the tray or pot if they die or appear diseased. Pot healthy cuttings up promptly once they recommence growth following rooting.

**Hardwood cuttings** are taken once the tissue becomes woody and the plant is dormant. Cuttings can be taken two weeks after leaf fall and before bud burst. Select healthy wood that was produced the previous summer. The wood should be about pencil thickness and cut into sections of approximately 20–25cm (8–10in). Several cuttings can be made from the same branch of some shrubs.

To take hardwood cuttings, make basal cuts just below a node, and upper cuts slightly above a bud. The upper cut should be slanted and the lower cut straight, so that a cutting is less likely to be inserted into the potting mix upside down. Once inserted all the tops of the cuttings should be slanted cuts. Bury cuttings vertically in moist sandy topsoil or sand.

The cuttings should not freeze, but must remain cool. In spring, remove the cuttings from storage and plant in a hotbed or other protected site with exposure to morning sun or filtered light. Leave 2.5–5cm (1–2in) of cutting above ground. Keep cuttings moist until a root system forms. Transplant the cuttings the following spring while they are still dormant.

## LAYERING SHRUBS

**1** *Choose a stem that will reach the ground without breaking and prepare the soil beneath it. In most cases, the native soil will be satisfactory, but if it is heavy clay, add some potting mix to improve its texture.*

**2** *Trim off any side shoots or leaves. Dig a shallow hole and bend the shoot down into it.*

**3** *To help hold the shoot in place, peg it down with a piece of bent wire.*

**4** *Fill in the hole and cover it with a stone. In many cases, the stone will be sufficient to hold the layer in place and a peg will not be required. The stone will also help to keep the area beneath it moist.*

**5** *It may take several months or even years for shrubs that are hard to propagate to layer but, eventually, new shoots will appear and the layer will have rooted. Sever it from its parent and pot it up into a container.*

**6** *If the roots are well developed, transfer the layer directly to its new site.*

## SIMPLE DIVISION

1 *Water the plant that is to be divided during the previous day. Carefully dig up a clump of the plant using a spade, in this case a Michaelmas daisy (Aster novi-belgii).*

2 *Insert two garden forks back-to-back into the plant and lever apart by pushing the handles together. Keep on dividing until the pieces are of the required size.*

3 *The pieces of the plant can then be replanted in the bed, but dig over the soil first, removing any weeds and adding some well-rotted organic material.*

4 *Alternatively, small pieces of the plant can be potted up individually. After watering, place these in a closed cold frame for a few days before hardening off.*

### DIVISION

Division is the cutting or breaking up of a crown or clump of suckers into segments. Each segment must have a bud and some roots to propagate successfully. These segments are replanted and grow into new plants identical to the parent. Most perennials should be lifted and divided when they become overgrown and begin to lose vigour. Vigorous growth in most perennials occurs on the outer segments of the clump. Old growth in the centre of the clump is discarded.

Carefully dig up the plant, loosening the roots and lifting it from the soil. Split apart the main clump with two spades or forks, or chop with a shovel or large knife if the clump is firmly massed. It is advisable to divide autumn-flowering perennials in spring, while those that flower in spring and summer are best divided in autumn.

### GRAFTING AND BUDDING

Grafting and budding involve inserting or attaching a part of one plant on to another so that both parts continue to grow. In grafting, you attach a short twig from a desirable variety with two or more buds (called a scion) to a seedling. This seedling is called the stock and forms the root system for the new plant, while the scion becomes the top growth. Budding involves inserting the bud from a desirable variety into a cut or slit in the bark of the stock. The bud develops into the whole top of the plant. You must match scions and buds with stocks according to their ability to grow together.

## CHIP BUDDING

1 *Select good bud wood that is free from blemishes and obvious damage, pests or diseases. If you are doing this in the summer, then you must first remove the leaves.*

2 *Remove the bud using a very sharp, flat-edged knife. Cut out the bud with a thin shaving of the wood below the bark and leave a "V" shape at the base.*

3 *Prepare the stock plant by cutting a "church window" shaped notch from the stem that is the same thickness as the chipped bud and leave a small notch cut into the base.*

4 *Place the bud into the notch, fitting the "V"-shaped base into the notch at the base of the "window cut".*

5 *Make sure that the bud fits snugly, with the edges of the bud-wood in contact with the edge of the "window" notch.*

6 *Secure the graft firmly with grafting tape to ensure that the join does not dry out. The graft will usually take in about 4–6 weeks in the summer but winter grafts can take longer.*

# THE GREENHOUSE ENVIRONMENT

*Greenhouses provide an environment in which levels of light and shade, temperature and moisture, and protection from the elements can be closely controlled and monitored. You can propagate plants to grow outside, protect tender plants from frosts and grow certain crops out of season. A basic understanding of the ways that the greenhouse environment can be controlled will help you on your way to a bumper harvest.*

Above: *Shading helps to keep temperatures down in the summer and also protects the plants from sun scorch.*

## LIGHT INTENSITY

Natural light has all the right wavelengths that plants need to function and grow successfully. Light intensities vary considerably during the year and gardeners often try to compensate for this by giving extra light to the plant. The quality of this light must be correct for the growth of plants, and light bulbs used to supplement natural light must be of a suitable daylight quality. Natural winter light intensity is often insufficient for certain crops. Conversely, summer light levels, especially when combined with elevated temperatures, can cause problems for other crops. Balanced growth requires good greenhouse design and proper planning for the light requirements of the crop. As a general rule, the ridge that runs along the middle of your greenhouse (if yours is a traditional "A"-shaped one) should always be orientated so that it runs east to west.

Above: *A maximum/minimum thermometer is an essential tool in helping you to judge the conditions in your greenhouse.*

## LIGHT READINGS WITH A METER

These should be taken inside the greenhouse and then compared with an outside reading. The difference between the two readings will indicate the percentage of available light transmitted into the greenhouse. A good tip here for those without a professional light meter is to use the automatic aperture reading on an SLR camera or a photographic light meter. It will not give actual figures, but will indicate to a certain extent just how much of the available light is getting through.

## ADDITIONAL LIGHTING

Supplementary lighting can be used to "top-up" existing daylight, especially in winter. You should always buy bulbs that give a full spectrum of light (the same quality as daylight – often sold or described as "grow lights"). Almost all bulbs for household use are short of the particular light wavelengths that plants need to produce food and grow successfully. Grow lights tend to use a lot of electricity and it may be cheaper to provide additional light for just a part of the greenhouse, suspending the lights above a crop that really needs the light. Grow lights are available as bulbs or strip lights and can sometimes be bought as special enclosed units.

## SHADING

This controls temperature and light. Shading is usually put in place in order to reduce summer temperatures (if they are excessive) or to protect young plants and shade-loving ones from very intense sunlight. Blinds, netting or white shade paint can all be effective.

## TEMPERATURE

Almost all plants like a fall in night-time temperature of about 4–6°C (7–10°F) below that in the day. Many commonly grown species have a relatively wide range of tolerances, but most grow best between about 16–24°C (60–76°F). All plants have maximum and minimum temperature tolerances that should never be exceeded.

You can take an average temperature reading inside the greenhouse using a maximum and minimum thermometer. Compare it with one taken outside. You should note, however, that more than just the outside temperature influences that of a greenhouse. The action of the sun, even on a relatively cold day, can result in temperatures being much higher inside than out. Wind is also a factor to consider that can cause a chilling effect far below the temperature average, rapidly cooling the glass and air nearby.

## HEATING SYSTEMS

Most heaters depend upon a hotbox or burner. These work by heating the air directly. They are more generally used

Above: *Some automated systems measure air temperature, and then turn on heat and open vents as necessary.*

Left: *Even a relatively small greenhouse can vastly increase the range of plants that you can grow in your garden.*

where there is no need to provide heat on a regular basis – in cold greenhouses, for example, or in polytunnels used for raising early hardy stock. Some enterprising gardeners link hot water pipes to their domestic heating systems to provide heating for the greenhouse. The disadvantage here is that the heat tends to be applied at times to suit the household but not the plants within the greenhouse.

### INSULATION

It is possible to insulate a greenhouse by providing additional layers within the structure to trap air. Bubble-wrap plastic is a popular method as it is easy to place in position and allows for the transmission of light. Such methods always reduce the amount of light transmitted, but will save upon heating costs. In addition to this, careful siting of the greenhouse can help to reduce the chilling effects of high winds.

### HUMIDITY

Most plants thrive in about 40 to 60 per cent humidity. Plants that are grouped together often set up their own small microclimate where the humidity is higher in the immediate vicinity. Much of the humidity requirement for a plant depends upon where it comes from. Rainforest plants often need 85 per cent or more humidity, whereas cacti need as little as 15 per cent (in cultivation). The humidity is also affected by other factors, notably temperature. Warm air can hold much more moisture than cooler air.

The need to increase humidity rises during the hotter months when it is harder to keep down the temperature in protected structures. Increasing the humidity also helps to slow down the water loss from leaves and may also help to prevent wilting or scorch.

Humidity should be raised by damping down (spraying a hose on hard surfaces, paths or under benches) on hot dry days. If there are only certain plants, such as young seedlings, that require elevated humidity, then these are best covered with a thin layer of clear plastic.

### AIR CIRCULATION

All plants need a constant supply of clean fresh air around them in order to grow healthily. Outdoors, normal wind movements would supply this, but in a greenhouse you will need to make provision for this.

Ventilators help control temperature and air flow. Roof vents should normally occupy the equivalent of 15 per cent of the floor space in order to be fully effective. They are normally a single structure that opens "window fashion" with a safety catch to keep them open to the required width. As with greenhouse design in general, there are many designs, most being simple variations on a theme. Side ventilators are also occasionally seen in some greenhouses. These are usually arranged in a "louvre type" fashion, with several overlapping strips that can be opened or closed with a small lever.

### CHECKING THE CONDITIONS

The greenhouse microclimate differs from the garden chiefly because the light intensity is lower, the temperature is higher and air turbulence is less. How you modify the environment largely depends on what you intend to grow. Winter salad crops need some additional heat, particularly on cold winter nights. Slightly tender, overwintering perennials may not need any heat unless the temperature drops very low. You must know what the environment will be even on cold winter nights. The only really accurate way to assess the suitability of an environment for plant growth is to take regular readings. Many devices exist to monitor the internal conditions within protected structures. These include thermostats for heating and automatic ventilators, although a seemingly endless array of humidification, automatic shading and watering devices are now available for small greenhouses.

### GREENHOUSE HYGIENE

Practising good hygiene is important in maintaining the health of the plants. Dead leaves and debris left lying about can harbour pests and diseases, as can badly affected plants if they are not removed promptly. Once a year, thoroughly clean all surfaces, including glass and glazing bars, with hot soapy water. This will pay dividends during the growing season by reducing the number of annually re-occurring pests and diseases. Where plants are grown in open borders, rotate crops or replace the soil with fresh topsoil every two or three years.

Above: *Bubble-wrap plastic is an ideal material with which to insulate the greenhouse in the winter.*

# GREENHOUSE CULTIVATION

*In a greenhouse you can hasten the arrival of spring by forcing hyacinths, tulips, azaleas and a whole variety of spring crops. You can also lengthen summer, with roses that bloom far into the autumn, and brighten winter with carnations, camellias and rare tropical flowers. You may also harvest tomatoes in mid-winter and vegetables or greens at any time of the year.*

Above: *Early crops and flowers can be raised in pots ready for planting out when the weather is warmer.*

## METHODS OF GROWING

Think carefully about how you plan to use your greenhouse and what plants you would like to grow there. The true art of greenhouse gardening lies in using every available area of space. This will involve planning the layout of the growing areas in the greenhouse and making a cropping plan to ensure that you not only use all of the available space, but also every "time space" within the growing calendar.

## GROWING IN OPEN GROUND

Many greenhouse plants will grow well in open soil borders. The soil can be prepared in a similar way to that used for borders outside. Remember that much of what benefits outdoor soil (digging and adding organic matter) is also good for indoor soil. The advantage is that the system is sustainable over a long period and can even be serviced as a small raised bed system to help maintain steady soil temperatures. Taller crops, such as tomatoes, are particularly well suited to growing in open borders in the greenhouse, but a whole range of both ornamentals and edible crops can also be grown in this way. Remember that if you intend to grow certain crops indoors – salad crops, tomatoes, legumes or cucumbers, for example – then you may need to rotate these, or in smaller spaces avoid growing them in open ground every second or third year. This is done for the same reasons that outdoor crops are rotated.

Above: *Staging can provide extra space in the greenhouse as well as a comfortable surface on which to work.*

Left: *You can grow crops in soil beds as well as in pots in the greenhouse.*

## GROWING IN POTS ON STAGING

Staging is essentially a shelf or shelves on which plants in pots are arranged. It enables the gardener to work at a comfortable height and is particularly useful for those who wish to raise seedlings and propagate plants. The area beneath the staging is somewhat shaded but by no means wasted as it can be used for overwintering dormant plants, growing ferns and other shade-lovers, and for some forms of propagation (lilies propagated from scales, for instance). It also provides the perfect place for propagators and can easily be adapted to become a propagating tent.

## USING GROW BAGS

Grow bags offer a good alternative to open beds in smaller greenhouses, where space is limited and no open beds exist. These can be purchased or you can easily make your own by filling a large plastic potting-mix bag with a mixture of garden compost and a little grit. Each bag will support four tomato plants and even greater numbers of smaller plants. Grow bags are ideal for raising sweet peas (*Lathyrus odoratus*) for use on patios or roof gardens where the rich deep soil in which they thrive is unavailable. They can equally be used to raise garden peas or beans.

## GROWING CLIMBING PLANTS

The last dimension in the greenhouse is the vertical one, ultimately to the roof. Lean-to greenhouses are especially useful for this, their back walls being well suited for growing such things as vines or kiwi. Even freestanding "apex" houses (those shaped like an "A" with a central ridge) can be used to raise climbing crops, such as cucumbers or melons, to say nothing of the thousands of delightful and colourful ornamental climbers that thrive in the greenhouse.

## A YEARLY GREENHOUSE CROPPING PLAN

The plan shown below is a sample of how a greenhouse can be used to be productive all year round. The essential point is that you plan what you want to grow. Once you have decided on this it is a relatively simple matter to make your greenhouse a productive space.

| GREENHOUSE TASK | MID-WINTER | LATE WINTER | EARLY SPRING | MID-SPRING |
|---|---|---|---|---|
| Edible crops | Sow seeds for early crops. Interplant with radishes. Sow early cabbage and cauliflower in pots. Bring strawberries in from frames. Top-dress vines and fruiting climbers. | Sow broad beans. Pot on early vegetable seedlings. Reduce young shoots of vines to one to two per spur and raise lowered rods back to the greenhouse side. | Sow the seeds of Brussels sprouts. Sow indoor tomato seed and make sowings of calendula, tagetes or similar in order to encourage beneficials and pollinators. Prick out seedlings. | Sow seed of outdoor tomatoes, celery, celeriac, melons and cucumbers. Harden off early vegetable plants. Tie new growth from vine rods on to wires. Remove side shoots of early tomatoes. |
| Ornamentals | Take cuttings of plants such as chrysanthemums. Bring bulb pots in for forcing. Pot on autumn-sown sweet peas into "long" pots. | Start off dahlia cuttings. Cut back and re-pot fuchsias and pelargoniums. Sow sweet peas (*Lathyrus odoratus*). Pot up cuttings of herbaceous plants. Sow herbaceous seed and begin sowing bedding plants. | Harden off early sweet peas. Pot up cuttings and sow seed of half-hardy annuals. Take cuttings. Prick out seedlings. Pot up summer bedding tubers and corms. | Finish sowing half-hardy bedding. Pot up cuttings and prick out seedlings. Make up summer tubs and hanging baskets for growing on. |
| General | Wash glass panes of greenhouse and frames. Keep conditions on the dry side. Be vigilant for winter pests and diseases. Provide heat as necessary. | Keep an eye on ventilation. Watch for pests and diseases. Keep conditions on the dry side. Remove dead or dying material from plants. Provide heat as necessary and ventilate. | Damp down on hot days and ventilate. Watch for pests and diseases. Begin to feed plants as growth increases. Dig, manure and top-dress borders ready for planting. | Damp down at least twice daily when hot and ventilate. Continue to watch for pests and diseases. Dig borders and manure if you have not already done so. |

| GREENHOUSE TASK | LATE SPRING | EARLY SUMMER | MID-SUMMER | LATE SUMMER |
|---|---|---|---|---|
| Edible crops | Plant greenhouse tomatoes into prepared borders or large pots of loam-based potting mix. Interplant with calendula and tagetes to encourage bees into the crop. Prick out celery and celeriac cuttings. | Thin grape trusses using vine scissors. Thin fruit if necessary on peaches growing under glass. Pick tomatoes regularly as they ripen. Pinch out and tie in melons and cucumbers as they reach their intended size. | Hand pollinate melons and cucumbers. Perform last thinning on grape trusses. Feed tomatoes with dried blood to develop uppermost trusses. | Remove lower leaves of tomatoes as fruit ripens. Support melons, removing leaves that shade the fruit. Harvest cucumbers. Sow seeds of winter leaf crops and companion plants. |
| Ornamentals | Harden off bedding plants. Place winter-flowering cyclamen in shade and allow to partially dry out. | Take cuttings of deciduous shrubs. Propagate houseplants. Sow seeds of spring bedding plants in frames. | Take cuttings of evergreen shrubs and deciduous species. Propagate houseplants. Sow seeds of biennials in frames. Re-start rested cyclamen corms. | Take cuttings of pelargoniums and fuchsias to act as "mother plants" for cuttings the next season. |
| General | Provide shade over sensitive crops. Feed plants regularly with a liquid "tea". Watch for pests and diseases and introduce biological control. | Water regularly. Continue potting on developing cuttings and seedlings of all plants. | Water regularly (twice daily in hot weather) and damp down two or three times daily to maintain humidity. | Continue potting on developing cuttings and seedlings. Continue to watch for pests and diseases and introduce biological control if necessary. |

| GREENHOUSE TASK | EARLY AUTUMN | MID-AUTUMN | LATE AUTUMN | EARLY WINTER |
|---|---|---|---|---|
| Edible crops | Cut melons as soon as they are ripe. Clear tomatoes as they finish. | Plant up winter leaf and salad crops, interplanting these with an appropriate companion planting. | Lift crowns of rhubarb for forcing and leave them on the surface for a week. | Sow seed of early onion varieties. Lift further crowns of rhubarb for forcing. Prune peach trees that are growing under glass. |
| Ornamentals | Take last semi-ripe cuttings and softwood cuttings. | Harden off spring bedding plants ready for planting. | Move bulbs for forcing into a frame to encourage top growth. Lift and pot up lily-of-the-valley for spring display. | Bring in bulbs for forced flowers. Stool back "mother" plants for early cuttings. |
| General | Decrease watering as days shorten. Pot on developing cuttings and seedlings of all plants. Remove shading and provide gentle heat on cold nights. | Pot on any remaining cuttings and seedlings. Pick over plants on a regular basis in order to remove dead or dying material. Provide gentle heat on cold nights. | Keep conditions on the dry side. Be vigilant for winter pests and diseases, as plants become more stressed due to low light levels. Provide heat as necessary. | Repair any damage to glass panes immediately it is noticed. Order seed for the coming season if you have not done so already. |

# COLD FRAMES AND CLOCHES

*Individual and multiple plant protectors are useful for covering the transplants or seedlings of warm-weather vegetables or flowers that are set out ahead of the normal planting season. These usually take the form of low plastic tunnels, cloches or individual bell jars. The colder the area in which you live, the greater their usefulness because they effectively extend the length of the normal growing season.*

Above: *This is a sturdy brick cold frame with a soil bed for growing winter and early spring vegetables.*

## COLD FRAMES

These enable you to sow summer flowers and vegetables some weeks before outdoor planting and may even allow for an extra crop within a season. They are relatively inexpensive, simple structures, providing a favourable environment for growing cool-weather crops in the very early spring, the autumn and even into the winter.

Cold frames have no outside energy requirements, relying on the sun as a source of heat. They collect heat when the sun's rays penetrate the light (the top cover) which is made from plastic, glass or fibreglass. The ideal location for a cold frame is facing the direction of the sun with a slight slope to ensure good drainage and maximum solar absorption. A sheltered spot against a wall or hedge is best. Sink the frame into the ground to provide extra protection, using the earth for insulation. Put a walkway to the front and adequate space behind the frame to help when removing the light.

Designs for cold frames vary. For example, some contain barrels that are painted black and filled with water. These absorb heat during the day and release it at night. Some cold frames are built with a very high back and a steep glass slope. Others are insulated very well and may also include moveable insulation. A simple method of providing insulation is to use sacks filled with leaves over the top of the frame and bales of straw or hay stacked against the sides at night in order to protect against freezing.

There is no standard-sized cold frame. The inside depth of the frame should be determined by the height of the plants that you plan to grow. Spring annuals, perennial seedlings or low over-wintering stock may need as little as a 30cm (12in) backboard and a 20cm (8in) front board. Potted plants may need a 38cm (15in) front board and a 45cm (18in) back board. A standard glass frame light is usually about 1 x 1.8m (3 x 6ft). Do not make the structure too wide for weeding and harvesting; a width of 1.2–1.5m (4–5ft) is convenient to reach across.

Cold frames are useful for hardening-off seedlings that were started indoors or in a greenhouse. This hardening-off period is important because seedlings can suffer serious setbacks if they are moved directly from the warmth and protection of the greenhouse to the garden. It is also possible to start cool-weather crops in the cold frame and either grow them to maturity or transplant them in the garden. Cold frames may also be useful for rooting the cuttings of deciduous and evergreen shrubs and trees, and the softwood cuttings of chrysanthemums, geraniums and fuchsias during the warmer months. Ventilation is most critical in late winter, early spring, and early autumn on clear, sunny days when temperatures may rise above 45°C (113°F). The light should be raised partially to prevent the build-up of extreme temperatures inside the frame. Lower or replace the light early each day in order to conserve some heat for the evening.

In summer, extreme heat and intensive sunlight can damage plants. You can avoid this by shading with a lath (a slatted wooden frame) or old bamboo window blinds. Water plants early so that they dry before dark; this helps to reduce disease problems.

## CLOCHES

Traditionally a bell-shaped glass cover, a cloche is a moveable structure that serves as a mini-greenhouse. Cloches can be used to protect transplanted tender plants from spring frosts. They also help to warm up the soil for crops sown directly in the soil.

Left: *When the seedlings are fully acclimatized and ready to be planted out, the lights or lids can be left off altogether.*

Above: *A rigid plastic cloche is easy to use. The sections butt up against each other and can be pegged into the soil. Endpieces are also available.*

Above: *Glass bell jars are simple cloches for covering one plant. They are expensive, but large plastic jars make a good, if not as attractive, alternative.*

The traditional or European cloche is usually built in 60cm (24in) sections that vary in height from 20–60cm (8–24in) and 40–65cm (16–26in) in width. It is made of four panes of glass held together with heavy galvanized wire fittings. It has a handle for ease in carrying and for operating the ventilation system. Several cloches placed end to end make a miniature greenhouse.

Plastic bottles with the bottoms cut out can provide protection for small individual plants. These will last a season or two, but will become brittle over time. Flexible fibreglass sheets held in an inverted "U"-shape by stiff wire hoops or small wooden stakes can be used to cover rows of plants.

A tunnel-like plant protector can be made with a 1.5m (5ft) strip of plastic or fleece laid over 1.8m (6ft) wire hoops placed 1m (3ft) apart. Elastic tiedowns over the top near each hoop will hold the plastic.

Temporary cloches can also be made by arching black, semi-rigid, plastic piping over the row or bed and sticking it into the ground on each side. Lay clear plastic over the arches. If the beds are enclosed with wood, attach brackets to the inside edges of the boxes or sink short pieces of pipe with a larger inside diameter along the sides to hold the arches. The arches can be used to support fleece or shade cloth to ward off both frost and bright sunlight. When this cloche is no longer needed, simply remove the plastic sheet and pipe ribs and store them until the following season.

### THE BOTTLE RADIATOR

In areas prone to late air frosts, this simple method can protect outdoor crops such as bush tomatoes. Fill a glass or plastic bottle with water and place it next to the plant. The sunlight will warm the water in the bottle, which will in turn release a gentle heat at night. This is sufficient to prevent cold shock to the plant and will ensure good growth and cropping. It can also be used in conjunction with a fleece covering to enhance the warming effect.

Left: *Old-fashioned cloches are particularly good for decorative vegetable gardens. However, they are also very expensive.*

Far left: *Upturned, clear plastic bottles with the bottoms cut out are ideal for using as mini-cloches, protecting individual plants. This is also an environmentally friendly technique.*

# PLANT HEALTH

The main concern for new organic gardeners is that their plants will be attacked by pests and diseases. There is an array of techniques to control these undesirables, although the organic gardener must first learn to recognize signs of distress. However, you are unlikely to experience more than a handful of the problems described, all of which are relatively easy to solve. Pests, for example, are eaten by creatures known as beneficials and so the ecology of the garden, once stabilized, will be enough to keep most problems at bay. There is always a technique to control more persistent problems and so ensure the health of your plants.

Left: *A scarecrow is a traditional way of protecting your crops from marauding birds. It can also be decorative and amusing.*

bove: *Companion plants such as these arigolds can provide welcome colour in e kitchen garden.*

Above: *Brightly coloured flowers can encourage a variety of beneficial insects into your garden.*

Above: *Decorative planting in the vegetable plot can provide additional colour and interest.*

# WHY PLANTS GET SICK

*Plants are prone to numerous ailments, some of which can be a serious threat to their survival. Pests and diseases are only one of the potential pitfalls that you will meet during a normal growing season. A basic knowledge of the other main factors that can affect plant health are all you will need to help your garden to flourish. While the sight of your plants suffering can be alarming, there are, in general, only a few potential health threats that you are likely to encounter.*

Above: *Large blocks of the same type of plant are easy for pests to locate and are therefore prone to attack.*

## FROST

This can cause serious problems and is actually more critical than average minimum temperatures. Most harmful are unexpected frosts that can cause severe damage even to hardy subjects, especially when they may have produced "soft" new growth.

While warm air rises, cold air will settle and collect in hollows and depressions. Cold air is laden with water vapour and is therefore heavier. Any valley or low-lying area is, therefore, a potential frost pocket. Cold air will accumulate in a depression and then back up the sloping sides as the build-up increases. Any barrier, such as a hedge or a wall, will obstruct the passage of the cold air and a frost pocket will form. Any plants growing in the vicinity will be exposed to the frost and may be damaged by it.

When the soil is frozen, water is no longer available to the plant and shallow-rooted plants are not able to access any water to replace that which they are losing through transpiration. The plant will dehydrate and the foliage will brown and shrivel. Ground frosts may also cause the soil to "heave" and plants will be lifted out of the ground.

Alternate freezing and thawing is often more damaging to the plant than the initial frost itself, especially for tender or half-hardy subjects such as bedding plants. Severe frost can split the bark on woody subjects and may also distort leaves.

The damage caused by frost is directly related to its duration. A temperature of -4°C (25°F) for one hour may cause little or no damage, while the same temperature for four hours may be disastrous.

## WATERLOGGING AND DROUGHT

The build-up of water in the soil, particularly where this occurs over a prolonged period of time, can be highly detrimental to the health of your plants. This is of greatest concern with plants that are not adapted to such waterlogged conditions. As a result, the roots of the plants will suffer and probably die from asphyxiation.

Left: *Planting crops among companion plants will make it more difficult for pests to locate them.*

Water shortage or drought only tends to occur during the summer months when temperatures and light intensity are at their peak. The most obvious sign of the effects of water shortage on a plant is when it wilts and loses its turgidity. Water shortage also causes plant functions to slow down dramatically and prolonged drought can result in permanent cell damage.

## WIND

The effects of wind damage to plants, especially woody trees and shrubs, are sometimes only too obvious. Wind often worsens extremes of temperature and drought. In severe cases of wind damage, trees can be broken and shrubs uprooted. The stronger the wind, the more damage is likely to occur.

## LIGHT IMBALANCES

A plant's growth is always directed towards the available light. Plants growing in shade often become drawn and etiolated. Conversely, strong sunlight damages plants by scorching the foliage. To prevent such problems it is best to select plants that will grow well in the prevailing site conditions.

## NUTRIENT IMBALANCES

Plants exhibit varying symptoms to a nutrient imbalance depending, in general, upon the severity of the problem. Symptoms of deficiency may include stunted growth, discoloured leaves (including mottling and interveinal coloration), the premature death of leaves and parts of the plant, twisted and distorted growth and poor root growth and development.

Right: *A healthy, flourishing border, which is free of pests and diseases, is the ultimate aim of all organic gardeners.*

The symptoms are usually noticed first on the shoot tips, although problems may appear on any part of the plant and in different stages of growth. Determining a cause may involve an analysis of the soil.

Any nutrient can be toxic to the plant if it is present in sufficiently high amounts or is out of balance with other elements in the growing medium.

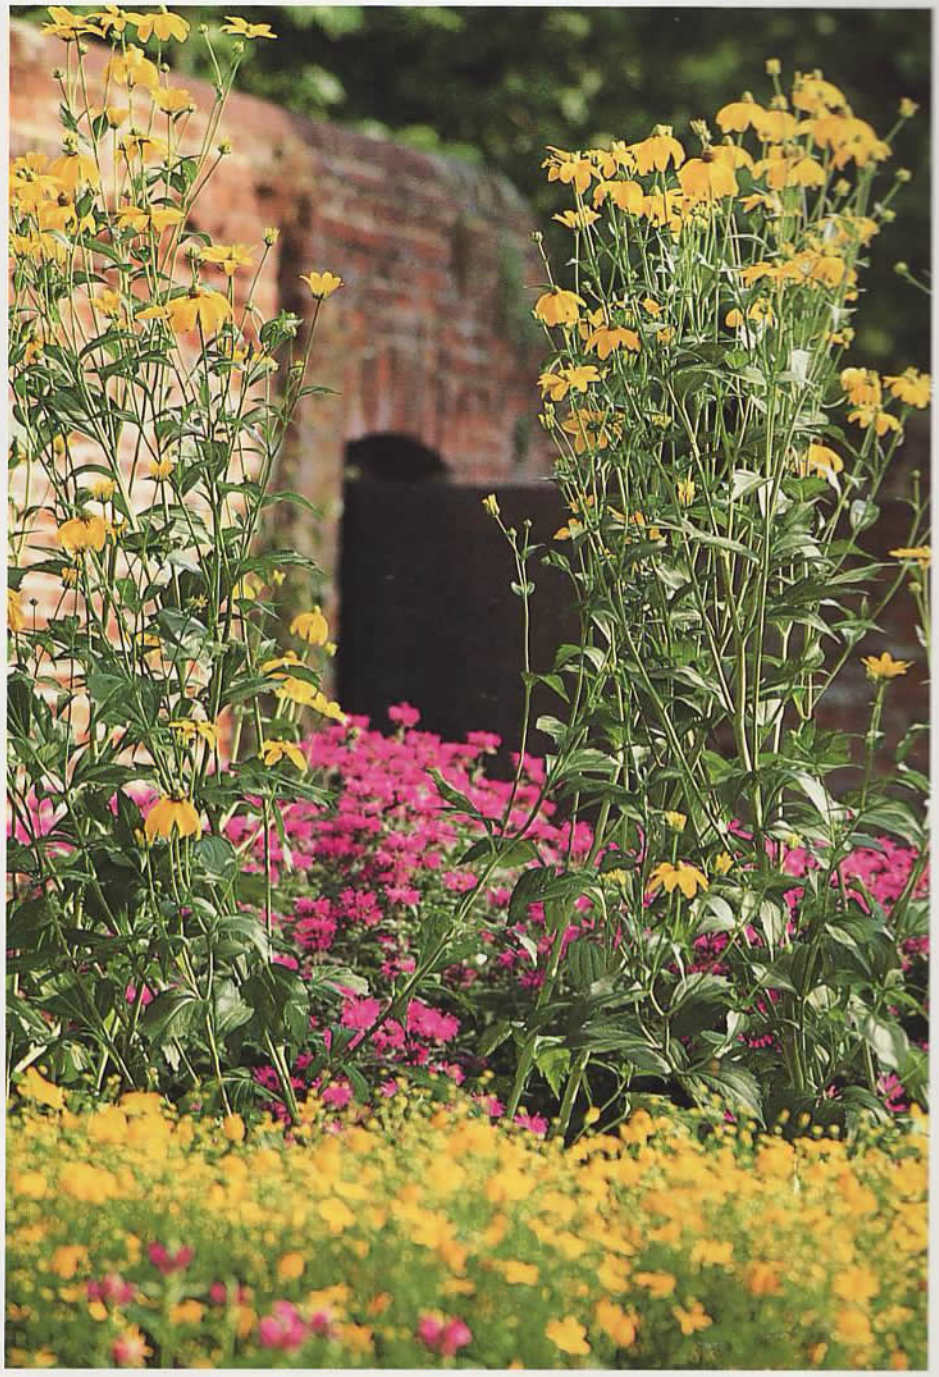
## POLLUTION

Specific symptoms of pollution may include leaves turning brown at the tips and margins, leaf discoloration or premature leaf fall. Growth may also be stunted.

Soil pollutant damage can be very severe and rapid in its effects on a plant and its growth. Common problems that you may encounter include extreme soil acidity or alkalinity, chemical toxicity, salt toxicity or pesticide residues. Of these, only soil acidity is relatively easy to cure. If serious pollution is suspected, then this requires specialist help. Such situations, however, are thankfully rare.

## PESTS AND DISEASES

It is important to bear in mind that a certain level of pest and disease invasion is normal even on healthy crops. However, it is also true to say that healthy vigorous plants are more resistant to serious attack than plants that are growing under stress. The best form of pest and disease control is obviously prevention. You will need to be able to find and recognize a range of pests and diseases in order to prevent outbreaks of them in your garden and, if necessary, take prompt action.

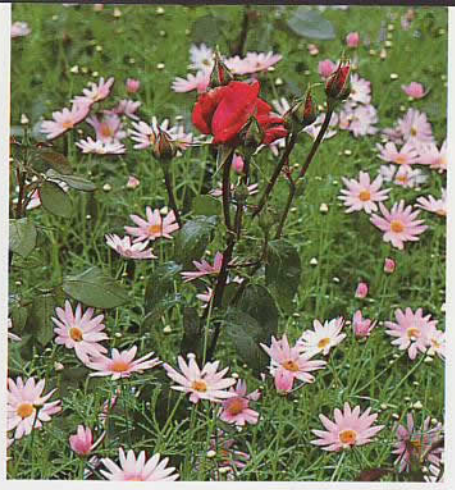


Left: *Healthy plants are often the result of careful selection according to the site conditions.*

Right: *It is very important to recognize potential problems before your plants suffer too much damage.*

# PREVENTING PROBLEMS

*Organic gardening is about working with nature to create an environment in which plants can withstand attack from pests and diseases, without you resorting to the use of harmful insecticides. If plants become infested with pests or diseases, they may fail to give a good display and crop yields can suffer. Prevention is better than cure, and a keen eye and regular checks will help you to anticipate and prevent the worst of any potential problems.*



Above: *A planting combination of roses and daisies will help to attract beneficial predators to the garden.*

## GOOD CULTURAL PRACTICE AND HYGIENE

Many pests and diseases can survive without a susceptible host even under the most unfavourable conditions. Myriad plant diseases survive from one growing season to the next on plant debris, in the soil, on seeds or on alternate hosts (some pests and diseases affect different plant species at different times of the year e.g. peach-potato aphid). This means it is vital to remove and properly dispose of any infected plant materials. It is also important for the organic gardener to be aware of the diseases that can threaten an individual crop and recognize the conditions in which these potential threats to plant health can thrive.

## GROW DISEASE-RESISTANT CULTIVARS

Plant varieties and cultivars were mostly chosen for other reasons than their disease-resistant qualities. Often they become so commonly grown that their diseases become widespread. Many plants have disease-resistant strains or cultivars, but this does not necessarily guarantee that they will be immune to a disease. However, they will be better able to resist the worst of its ravages.

Above: *Place straw under growing strawberries in order to protect them from rot and soil-dwelling pests.*

Above: *The regular washing down of the glass panes in a greenhouse can reduce the build-up of disease-causing organisms.*

Right: *Regular deadheading of old or damaged blooms will help to reduce the spread of some fungal diseases.*

## AVOID PLANT STRESS

A plant that is stressed – by drought or an unfavourable temperature, for example – will be predisposed to pest or disease attack. Plants that are not subjected to higher levels of stress than they can cope with will remain healthy and better able to deal with potential attackers.

Stressed plants often show signs of physical disorders (e.g. being tall, drawn and pale due to lack of light). These can be due to the weather, being wrongly sited, nutrient imbalance or the presence of a toxic substance in the air or soil. Physically stressed plants may become sicker than if a pest- or disease-causing organism actually had invaded them. Stress can kill a plant if the problem is not quickly remedied.

## RIGHT PLANT, RIGHT PLACE

Plants all have their preferred locations and the occurrence or lack of a particular environmental factor or factors will ultimately determine whether a plant will prosper in the position in which it has been planted. Ferns, for example, need a cool moist site. Placing one in a hot sunny site will lead to its death as it struggles to keep its moisture. Plants that become stressed will neither grow as well, nor be as disease-resistant, as they would otherwise. Choosing an appropriate site in the first place will at least help to ensure the initial health of your plants and will render them more able to resist other potential threats to their health.

## RECOGNIZING THE PROBLEM

Organic gardeners who understand pest life-cycles and behaviour are better able to determine when control will be most effective. Insects living in your garden are all part of nature's complex ecosystems and food chains. Less than one per cent of species that you are likely to encounter are considered pests. Since few insects are actually harmful, organic gardeners must learn which are pests, which are beneficials, and which ones will have no effect on the garden whatsoever.

Left: *Always choose plants that are suited to the site. Alkaline soils – indicated here by the pink flower of this hydrangea – will not suit certain plant species.*

Despite the fact that they are not always popular, insects play an important role in our gardens. Beneficial insects, such as bees, are necessary in the organic garden to pollinate fruit and some vegetable crops. Others, such as springtails, also help to break down dead plant tissue, while wasps and ground beetles capture and eat other pest insects and are called predators. Wasps and midges have larvae that attack pests by living inside their bodies and are called parasitoids. Organic gardeners must learn to cherish this "willing army" of helpers in their gardens.

## PEST AND DISEASE CYCLES

Often gardeners believe that their plants have been attacked overnight. This may be true in the case of damping-off disease or with larger pests such as rabbits. More often, however, much has occurred before the symptoms are actually visible.

The pathogen (the pest- or disease-causing organism) must be introduced (inoculated) to the host plant. Most pathogens either move by themselves (as with most pests) or must be carried to the host plant (as with the vast majority of diseases). Rain, wind, insects, birds and people usually spread plant diseases.

Splashing rain carries spores of apple scab fungus from infected apple leaves to uninfected leaves. Wind blows fungal spores from plant to plant, while aphids and whiteflies transmit many common plant diseases. Believe it or not, smokers can transmit tobacco mosaic virus from a cigarette to tomato plants.

Once the pathogen has been transferred to the host plant, it begins to multiply, change or grow into a form that can then enter the host. In many fungal diseases, the pathogen arrives on the plant as a spore, which must germinate before it can begin to grow and invade the plant. Once the fungal spore germinates, it sends out thread-like tubes called hyphae. These penetrate the plant through wounds or natural pores in the outer skin of leaves, stems and roots. The roots of bedding plants that have been damaged during transplanting are a common entry point for root-rotting fungi. A single aphid that lands on a plant can give birth to a clone every twelve hours and can eventually form a small thriving colony within a few days, leaving the gardener with the impression that it suddenly appeared.

Once established, pests or diseases can grow or increase in number and begin damaging plant tissue. As they consume nutrients or plant tissue, evidence of the damage to the plant begins to appear. Symptoms may be seen on any plant parts and include mottling, dwarfing, distortion, discoloration, wilting, shrivelling or holes and notching in the margins of leaves. The first signs of pest infestation may not appear until well after the insect has laid its eggs and disappeared.

Seeds or cuttings from infected plants will also transmit disease. Certified organic seed guarantees that at the time of sale the seeds are free of all diseases. Always try to obtain disease-free stock as this should guarantee that the plant is not infected and will not introduce disease into your garden. This is particularly important with plants such as roses as well as crop plants like raspberries and other small fruits.

Pest insects and mites may carry diseases that infect plants. Organic gardeners use the term "pest management" rather than pest control or pest eradication. It is impossible to eradicate pests from your garden completely. The best option is to try to keep pest numbers low in order to minimize the damage that they can cause in your garden.

## ADOPT AN INTEGRATED STRATEGY

Organic gardeners must learn how to use a range of pest management techniques, such as introducing beneficial predators into their gardens (often referred to as biological controls), making gardens less attractive to harmful pests, and encouraging conditions in the garden that favour beneficial predators of all types (cultural controls).

Left: *Composting is the best way of recycling garden waste, but you must never compost material that is diseased.*

# PLANT PESTS

*Pests can be described as those creatures that harm your garden plants and, if left unchecked, they can quickly cause a great deal of damage. There is a huge army of these pests, but most organic gardeners are unlikely to encounter the vast majority of them. A basic knowledge of the commonest types that occur in domestic gardens is all that you should need to be familiar with in order to protect your plants and guarantee their health and successful growth.*

Above: *Pests may well be present before symptoms appear. Close examination may reveal them before the plants start to suffer.*

### HOW CAN YOU TELL IF A PEST IS A PROBLEM OR NOT?

Deciding whether a pest is a problem or not is very much a matter of opinion. Commercial growers assess the importance of a pest in terms of their financial losses. Domestic organic gardeners, however, tend to grow fewer plants or crops and mainly grow these for their beauty or for the pleasure of eating home-grown produce. The final decision as to the importance of a pest will rely upon the circumstances and experience of individual gardeners. All organic gardeners must be willing to accept a certain number of pests in their garden as these form part of the intricate food webs that result in natural control. If there are no pests, then the animals that eat them will disappear and open the door to future, potentially serious, pest outbreaks.

### RECOGNIZING PESTS

It is important that you are able to accurately identify a pest that has been attacking your plants so that you can take the appropriate action. Just because an insect is seen walking on an affected plant does not mean that it is the one causing the damage. The only real way to control pests involves getting to know them. Many pests produce characteristic symptoms that make it possible to diagnose the cause with relative certainty. Some have a wide range of host plants, and symptoms may not always be as conspicuous on all affected plants. Close examination – perhaps with a hand lens – may be necessary for the final diagnosis. With careful observation and experience, it is possible to keep one step ahead of the pests in your garden.

### CONTROL OPTIONS

It is important to control pests before they become a problem. A single black bean aphid (*Aphis fabae*) that lands on a broad bean at the start of the summer could theoretically give rise to 2,000,000,000,000,000 aphids by the start of the autumn. This would be about a million tons of aphids. Numbers such as this are impossible but it does go to show that early control is essential. Quantities such as those quoted in the aphid example cannot occur as the food supply would run out before this can happen. In addition, a whole host of predators eat them. In just a few days, however, pests can cause considerable damage and quick action is needed if you are to save your plants. Organic gardeners must employ a full range of control measures to ensure their plants survive this seasonal invasion, including cultural practices (crop rotation, good hygiene and encouraging biodiversity), physical controls (hand picking, traps, repellents and barriers) and biological control (using other animals that naturally eat pests). These are covered more extensively later in this section but for now it is important to stress that pests can only really be controlled by an integrated strategy that uses a variety of techniques.

### CAN PESTS BE TOLERATED?

It is worth pointing out that we tend to be unduly concerned with pests damaging our plants. Supermarkets have conditioned us to expect blemish-free produce. We need to judge the overall health of a plant rather than react when we see a pest. If there were no pests in the garden, then there would be no predators. Step back and look at the whole picture and remember that everything, even pests, has its place in nature. They all add to the interest and diversity that is the most unique quality of an organic garden.

Above: *Birds can be serious pests in the garden. Here, large bites have been taken out of a brassica.*

Above: *Rabbits can devastate a garden overnight, leaving nothing but chewed off stumps as a result of their visit.*

Above: *Although fascinating to watch, squirrels are a garden pest and are closely related to rats.*

## COMMON PESTS

There is a seemingly endless array of garden creatures that are waiting to devour and attack your garden plants. The most common pests are almost worldwide in their distribution, but they can be controlled relatively easily. It can be discouraging to see how many potential pests may attack your garden, but it is important to bear in mind that you will only encounter a handful of these in your gardening career.

| PEST | | PLANTS AT RISK | TREATMENT |
|---|---|---|---|
| **Ants and termites** | | Ants are not really pests, but they "farm" aphids for sticky sugar. Termites can attack some woody species. | Few organic treatments, but baits based on borax are useful. Use a herbal spray of essential oil (citronella and lavender) or lukewarm water as a repellent. |
| **Aphids** | | Most cultivated plants growing in the open, under glass or indoors. | Encourage beneficial insects to feed on them. Organic insecticidal soap can also be useful, particularly if the aphids are being "farmed" by ants. |
| **Birds** | | Some birds will attack fruit and brassicas as well as brightly coloured flowers, including blossom. | Bird scarers may be employed as a deterrent and netting will also provide cover for individual crops and plants. |
| **Cabbage root fly** | | The small maggots grow and develop on and within the roots of the developing cabbage plant. | Place a collar around newly planted seedlings, sinking it into the ground to prevent the newly hatched maggot from reaching the plant roots. |
| **Carrot fly** | | These root-feeding maggots feed on carrots. | Try companion planting and avoid large monocultures of carrots. Erect plastic or fleece barriers, about 45–50cm (18–20in) high and 2–3m (6½–10ft) apart. |
| **Caterpillars** | | Many different species of plant, especially those in the cabbage family. | Birds and other predators will reduce populations. Biological control, using a bacterial agent, and pesticides such as derris. Hand-pick off individual plants. |
| **Chafers** | | Raspberries, strawberries, potatoes, lettuce, young trees, lawns and some herbaceous perennials. | Keep the ground weed-free, and well cultivated in order to reduce the number of bugs. Roll lawns in late spring. |
| **Deer** | | Browse on garden plants. Male deer rub their antlers against trees, causing damage to the bark. | Notoriously difficult to control, often best kept out by fencing. Repellents are available, based upon formulae such as bear or even lion droppings. |
| **Fruit flies** | | Troublesome on softer fruits in warm conditions, especially tomatoes. | Cover the fruit with a small piece of rag. Paper bags are also good to use, but can be difficult to get around a truss of tomatoes. |
| **Gall mites and wasps** | | These pests affect a wide range of trees and shrubs, especially oak trees. | Generally not problematic or life-threatening. They are a good indicator of healthy biodiversity in a garden. |
| **Leaf hoppers** | | There are many different types, affecting a wide range of plant species. | Difficult to control. Remove dead leaves to reduce overwintering eggs and nymphs. Encourage predators such as lacewings. |
| **Leaf miners** | | There are many hundreds of species that all have their preferred host species. | Hand-picking of severely affected leaves. Biological controls exist but the problem is rarely serious enough to warrant their artificial introduction. |
| **Leather-jackets** | | Can be a nuisance, especially of turf grass. They feed on roots just below the soil surface. | Can be difficult to control. Damp sacking over the soil can lure them up to the surface where they can be hand-picked or left for birds to eat. |

| PEST | | PLANTS AT RISK | TREATMENT |
|---|---|---|---|
| **Mealy bugs** | | Suck the sap of many species and produce a sticky honeydew that supports the growth of sooty moulds. | Biological controls are available. Cultural control is more difficult and involves drenching with an organic soap solution and then rinsing. |
| **Mites** | | A common pest of many plants, especially those growing in hot dry conditions. | Biological controls are available. For a cultural control, improve humidity or spray foliage with an organic soap solution and then rinse. |
| **Moles** | | Damage roots by lifting small newly planted trees. Tunnel under lawns, making them a serious pest. | Best controlled by trapping or using repellents. Sonic repellent devices are rarely effective. Removing one mole can simply "open the door" to another. |
| **Nematodes (eelworms)** | | A few species cause disease-like symptoms. A problem when the same plants are grown in the same place. | Regular crop rotations can help to reduce damage. If numbers build up or plants become badly affected, avoid growing the affected species. |
| **Rabbits and hares, squirrels, voles and mice** | | Rabbits gnaw shoots. Mice and voles eat small bulbs and corms in winter. They all ring-bark young trees. | They may be trapped or a variety of repellents are available. Tree and shrub shelters are useful against voles and mice as is fencing for rabbits and hares. |
| **Sawflies** | | Developing larvae eat plant tissue. Fruit sawflies are notorious. Slugworm sawfly attack ornamentals. | Control slugworm by applying insecticidal soap. Control fruit sawfly larvae with derris. Both these treatments reduce numbers of beneficial insect predators. |
| **Scale insects** | | Several species, some of which have specific host plants. | A cultural control consists of swabbing woody stems with a strong organic soap solution or pruning and removing affected parts. |
| **Sciarid fly (fungus gnat)** | | Tiny flies that feed on soil fungus. The larvae attack the roots of young plants in water-logged potting mix. | Control by preventing the potting mix becoming too wet, although biological controls of nematodes are also available. |
| **Slugs and snails** | | Common pests of a wide variety of plants. Snails, in particular, cause damage and defoliation of plants. | Often difficult to control although they can be caught in traps containing beer. A variety of barriers and deterrents are also available. |
| **Thrips** | | Small insects suck the sap of soft foliage and attack flowers. Rarely a problem outside in cooler climates. | Remove seriously damaged foliage. Several natural predators (usually mites) are available for use against thrips. |
| **Weevils** | | Larvae attack roots, stems or flowers and fruit of a range of plants. Adults feed on affected plants. | Wet acidic composts favour ground-living types such as vine weevil. Biological control possible with parasitic nematodes if temperatures sufficiently high. |
| **Whiteflies** | | A greenhouse pest in cooler climates that may occur outside in warmer areas. | Biological controls are available but the best option can be to avoid growing susceptible species. |
| **Woodlice (pill bugs)** | | Usually a pest indoors of crops like cucumbers. May chew through young seedlings. | Often more of an indication of poor hygiene than a problem in itself. A sign that you must clean up the greenhouse. |

# PLANT DISEASES

*The early detection of plant disease can help to halt the widespread infestation of your crop. Try to establish a routine of regularly checking your plants and crops. Look closely for any telltale signs, using a hand lens if necessary. Remember that the first or most obvious symptom may not always be the only one or even the most important. Always check to see if there are other symptoms to ensure that you get the full picture before making your final diagnosis.*

Above: *Modern rose varieties are highly susceptible to diseases such as blackspot and mildew.*

## RECOGNIZING PLANT DISEASES

Vigilance is the key to success in controlling plant disease. Carefully inspect leaves, stems, roots, flowers and fruits for any sign of disease. You may even find it useful to cut open a branch or stem to look for problems such as discoloration of the tissue, which may explain leaf or stem wilting and sudden wilting of a section of or a whole plant.

Stand back and look at the overall picture. Consider the whole environment. This will include the weather, soil, the stage of development of the plant (and any pathogens present), cultural practices and the condition of other plants in the area. All of this information can help to indicate what may be wrong with the plant. Remember that a plant growing in the wrong location may be stressed.

Try to determine when the symptoms became apparent. The onset of a problem may be due to a cultural practice, the seasonal appearance of a disease or insect, or a weather-related event. Remember that long-term stress is slow to appear, taking a year or more at times.

Try to determine whether the problem is spreading, as this may indicate that it is a disease. Check whether plants of other species have been affected, as diseases are usually (but not always) species-specific. Problems caused by environmental factors do not spread, although the symptoms may become more severe.

You must know what the plant should look like in order to be able to recognize any abnormalities. Reading up a little on the species that you are growing in your garden can help you to make a more accurate diagnosis of the problem.

Remember that there is usually no single cause of a disease infestation. The primary cause may be associated with cultural or environmental conditions. And just as there is probably no single cause, there is usually no single symptom.

When you are attempting to diagnose the cause of plant illness, always inspect symptoms that appear on parts that are still alive (or at least partially alive). Dead plants are often invaded by secondary infestations of decomposer fungi, which may hide the original problem. If possible, make an examination of the entire plant, including roots, although this may not be possible for large specimens such as trees.

Left: *Although a plant may be in obvious distress, closer examination may be needed to properly determine the cause.*

Right: *Disease-causing organisms can enter a plant each time it is cut or pruned.*

## CONTROL OPTIONS

Ultimately, where a serious disease is suspected, it may be advisable to avoid growing susceptible species altogether, or, in the case of fruit and vegetables, to rotate the crop as part of a regular cycle. Make notes that provide details on disease occurrence (the type of disease and when it appeared), the plants affected, the weather and environmental conditions in your garden each year. By doing this you can better anticipate what problems are likely to occur in your garden during the growing season.

Finally, remember that even the best gardeners lose plants to disease. This is only serious when large numbers of plants are affected. A diverse garden will contain other highlights, and diseases will claim only a fraction of the planting.

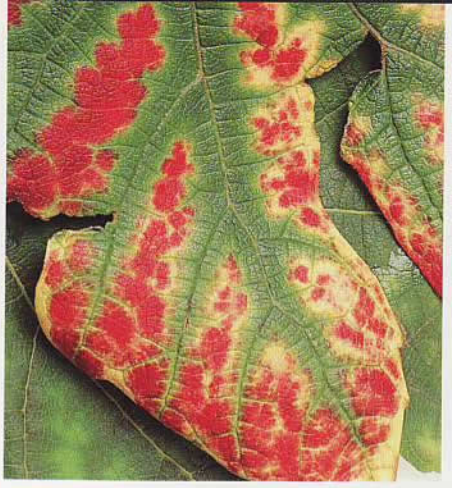
## COMMON DISEASES

There are all kinds of diseases that can affect your plants. Most of these are mercifully rare, but every garden will suffer from its share of diseases during the growing season. Most of these conditions are relatively easy to deal with, but a correct diagnosis is essential. As always, it is preferable to try to prevent these diseases taking hold and spreading in the first place rather than treating them when they occur.

| DISEASE | | PLANTS AT RISK AND THE SYMPTOMS | TREATMENT |
|---|---|---|---|
| **Bacterial canker** | | Many trees and shrubs. Reduces vigour and the rate of growth of the affected plant. Branches become girdled and die back. A sticky secretion will ooze from cracks or welts in the bark. | Difficult to control once a plant is infected. Confine the problem to one specimen by cleaning pruning tools between cuts and before moving on to another specimen of the same type. |
| **Blackspot** | | A common fungal disease of roses, which is most prevalent on modern hybrid tea and floribunda types. Black spots appear, primarily on the leaves and sometimes on the stems as well. | Prune bush roses into a goblet shape. Use disease-resistant cultivars. Dust affected plants with sulphur early and intermittently throughout the growing season. |
| **Bracket fungus** | | This disease can affect all types of tree. Bracket fungi are the fruiting bodies of fungi that either parasitize healthy heart wood or, more commonly, decay heart wood that is already dead. | Many affected trees live for many years and need only be felled if they present a risk of collapse. |
| **Common scab of apple** | | A bacterial disease that causes the formation of large (albeit harmless) scabs on the surface of the apples. Commonly encountered in damp weather and on trees with crowded branches. | Rake up and dispose of affected leaves. Prune out cracked or scabby shoots to remove places for the fungus to overwinter. |
| **Coral spot** | | A common fungus affecting many woody plant species. Appears as pink or bright red, raised pustules on wood that is showing signs of dieback. | Prune out infected tissue and destroy it. Regular "hygienic pruning" can help to prevent it taking hold in the first place. |
| **Downy mildew** | | A group of fungal diseases that affects a wide range of plants. Appears as a white coating over leaves that display distended growth, browning and wilting. Thrives in warm moist conditions. | Dust with sulphur or spray with Bordeaux mixture to form a protective barrier against the spores. Note that these are both easily washed off by watering or rain. |
| **Fireblight** | | Attacks plants of the Rosaceae family, notably apples, pears, plums, cherries, pyracanthas, cotoneasters and roses. The affected plant dies back rapidly from the branch tip. | Remove and destroy all affected material, cutting back to at least 50cm (20in) below the point of infection. Best to remove diseased plants, replacing them with a non-susceptible tree or shrub. |
| **Fungal canker** | | Affects many woody plants. The bark tissue begins to peel and flake away around the affected tissue in concentric rings. | Prune out the affected material, about 15cm (6in) below the point of infection, and burn it. Clean tools with disinfectant between cuts and especially between pruning individual plants. |
| **Honey fungus** | | A soil-dwelling fungus that parasitizes the roots of woody plants. Leaves tend to discolour and wilt and fail to develop in the spring. Ultimately, this can weaken and kill the plant. | Difficult to control organically. It may be best to grow herbaceous plants in affected areas for two to three years before attempting to replant woody plants there. |
| **Mosaic virus** | | This group of viruses affects a very large number of species and is characterized by an irregular, angular mottling or streaking of the leaves. | Winged insects that feed on plants, then migrate to another, can rapidly spread the virus. Control the pests themselves where possible. |
| **Phytophthora** | | A soil-borne fungal disease that affects many species of woody plants, particularly conifers. Branches die back, often very quickly. Serious infection may cause death for a large proportion of the root system and severe dieback of top growth. | There is no cure for this condition and the removal of badly affected plants may be the only answer. The disease is often restricted to damp or heavy soils, although prolonged wet weather can result in outbreaks. |
| **Powdery mildew** | | Affects many plant species, with asters being especially prone. The leaves become covered with white powdery patches that may distort growth or even cause leaf drop in severe cases. Thrives in warm, humid or wet conditions. | Sulphur and Bordeaux mixture can provide protection, but these are easily washed off in wet conditions. Avoid growing susceptible species if conditions favour the spread of the disease. |
| **Rust** | | A common fungal disease affecting many species. Characterized by rusty coloured patches or spots, known as pustules, on leaves. Tissue around the pustules yellows and dies, and this, in turn, may distort growth or cause leaf drop in severe cases. | Commonly seen on soils rich in nitrogen. It may have a noticeable effect on seasonal crops or those grown for their leaves. Bordeaux mixture can reduce its spread but it is difficult to control completely. Avoid susceptible crops and varieties if the problem is persistent. |
| **Silverleaf** | | Affects both fruiting and ornamental species of *Prunus*. The leaves on some branches gain a silvery sheen, gradually dying back a year or two later. A purple fungal growth appears on the dead tissue. | The affected wood should be pruned out below the point of infection and disposed of in late summer after fruit has set. Badly infected specimens should be removed completely and disposed of, preferably by burning. |
| **Stem rot** | | Attacks trees and larger woody plants. Stems and branches gradually become hollow. | Smaller trees or shrubs may be much more seriously affected and may be best removed if their condition deteriorates too much. |

# PLANT DISORDERS

*Many external factors can affect garden plants. Weather seldom does what we want it to – there is either too little or too much rain or it is too cold or too hot. If you combine these climatic disappointments with other factors that can affect your plants, such as pollution or nutrient deficiencies, you will see why these difficult conditions can produce a number of disease-like symptoms. They can all put severe stress on an ornamental plant or crop and so precipitate attack from living organisms.*



Above: *Nutrient deficiencies can cause discoloration of the leaves. This plant is short of magnesium.*

## RECOGNIZING DISORDERS

Plants can be susceptible to a long list of outside forces. Extremes of weather, nutrient deficiencies and physical damage can all take their toll on the health and vigour of a plant. Other environmental factors, such as too much or too little water or pollutants in the soil, can also encourage disease-like symptoms.

Soil pollution can be caused by nutrient deficiency, misapplied fertilizer (resulting in too much nutrient and, therefore, toxicity), spilt lawnmower fuel (perhaps due to careless filling) or buried inert material. Airborne pollution can be more insidious and more difficult to determine or detect.

Weather events such as high winds or frost may go unnoticed if you are not there to witness them. A huge storm will leave evidence in its wake. The effect of a sharp early morning frost, however, or a steady drying wind on a sunny afternoon may not show the damage caused until several days have passed. Often frost occurs in the hours just before daybreak and quickly disappears to leave a fine sunny morning.

Disease can result from a combination of factors, affecting growing conditions and actual disease-causing organisms. Plants may initially be placed under stress – by high winds or frost, for example – making them vulnerable to attack by living agents. For instance, drought may damage roots, which in turn renders them more liable to infection by fungal diseases.

It is important to determine whether the distress that your plant is suffering is the result of a pathogen or due to a problem in the environment. In order to work out which of these is responsible, look to see if the occurrence of ill health is random or uniform in terms of its distribution. As a general rule of thumb, randomly distributed symptoms on injured plants are usually caused by a living factor, such as infectious diseases or a pest. In addition to this, infestations, particularly those caused by diseases, tend to radiate out from central points. Uniform patterns are generally associated with non-living or non-infectious agents such as poisons, fertilizers, environmental stress or mechanical damage.

Above: *Drought is a common cause of stress in potted plants, damaging both roots and shoots.*

## CONTROL OPTIONS

If the cause of the problem is physical, you will need to find out whether it is due to a recurring environmental factor inherent in the site, such as constant buffeting by strong winds, or whether it is caused by "one-off" events such as unseasonable frosts or contamination from a careless neighbour's weedkiller spray. Some factors can be removed, such as polluted soil, and windbreaks can be planted and fleece draped over tender specimens on cold nights. If plants continue to be affected, it could be that the plant is in the wrong place and you may have to try it elsewhere.

Left: *Plants sometimes show unusual growth patterns in response to environmental conditions. Here, the growth of a tree has been affected by the wind.*

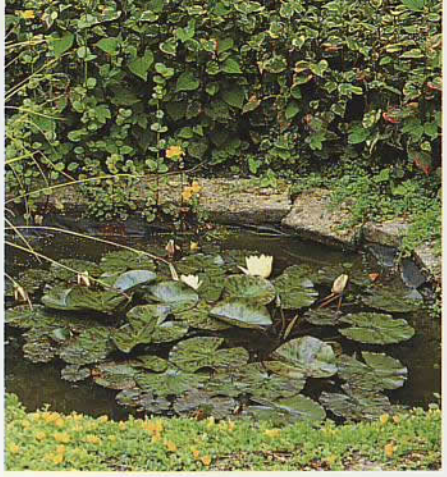
## COMMON DISORDERS

Disorders are the result of either an imbalance of essential nutrients or of a range of stresses that are caused by adverse or difficult environmental conditions. Many of the disorders and conditions described here can resemble diseases. This means that is very important for you to diagnose the cause of the distress in the plant before taking any remedial action. A plant disorder will call for a different response to a plant disease.

| CONDITION | | PROBABLE CAUSE | TREATMENT |
|---|---|---|---|
| Bare patches or areas of poor plant establishment | | The patchy establishment of cover crops or turf can be due to soil compaction or underground obstructions. Soil can easily become compacted if it is walked on a lot, particularly when it is wet. Buried obstructions such as rubble can also cause similar growth distortions. | Remove all buried rubble prior to planting or replanting. Relieve compaction by cultivating and replant if required. |
| Blackening of leaf tips | | Usually the result of overwatering, particularly with container-grown plants. The waterlogged soil or potting mix forces oxygen out of the soil, thereby suffocating the roots which suffer a form of drought-stress. | Do not water until the soil or potting mix dries out a little. Check to see if plants need watering before doing so. |
| Etiolation | | Sun-loving plants kept in low light conditions quickly become starved and will be significantly weakened. If kept in these conditions for any length of time, the plant will eventually die. | Choose specimens that are appropriate for the light levels in the garden. |
| Leaf blackening | | Frost damage on buds and leaves in early spring, even to hardy specimens, is usually noticed on new growth that has not yet become acclimatized. It is the sudden shock that often causes the problem, not the actual temperature itself. | Cover slightly tender plants with fleece in the winter. Lightly spray plants with water in the evening to help protect against late frosts. |
| Leaf scorch | | High winds and bright sunlight, especially on shade-loving species. Some plants can also be damaged by watering in bright sunlight, by providing too little or too much water or by applying too much fertilizer to the soil. Hail can also cause leaf spotting or holes. | Water in the evening. Choose wind-resistant species, if appropriate. Apply fertilizer at recommended rates. Do not over- or under-water plants. |
| Mechanical or physical damage | | High winds, which are especially damaging to deciduous woody plants in full leaf. Herbaceous plants can easily break if not adequately staked, as may newly planted trees and shrubs. Snow can snap the branches of conifers and evergreens. Visiting animals can also flatten or snap garden plants. | Stake plants firmly and ensure that animals are excluded from areas where plants could be damaged. |
| Nutrient deficiency | | A lack of or too much of a particular nutrient. Nutrients can also become in short supply if other nutrients are present in large amounts. | Deficiencies are best treated with the application of fertilizer or choose plants that are adapted to deal with the site conditions. |
| Poisoned ground | | Leaked fuel or lubricants used in construction work can leave the ground contaminated. This is usually more of a problem in gardens attached to modern houses. Underground gas pipes can leak, flooding the ground with gas that is lethal to plant roots. Other chemical spillages could come from machinery such as a lawnmower. | Remove all affected soil and replace with fresh topsoil. If pipes are leaking, make sure that they are fixed before replacing soil. Fill lawnmowers with fuel over a plastic sheet. |
| Root girdling | | This can cause instability and the collapse of larger trees and shrubs. Tree and shrub roots become woody following the first year's growth and, if these are constrained in round pots, they tend to grow in spirals. | Try to use bare-rooted stock whenever possible. Tease out roots from the rootball immediately prior to planting. |
| Wilting | | A normal response in many plants to either a lack of water or high temperatures, and not necessarily a cause for great concern. Ligularias habitually wilt on hot summer afternoons, even when planted in wet ground, only to "pick up" and show no ill effects later. | Treatment may not always be necessary. Check the soil first to see if it is dry. If not, wait until the evening to see if the plant shows any signs of improvement. |

# BENEFICIAL PREDATORS

*A thriving population of natural predators and parasites can significantly help to keep pest populations down. The organic gardener must strive to create and maintain an environment in which these welcome visitors to the garden or greenhouse can prosper. Above all, this means avoiding pesticides, which can wipe out beneficial predators and so upset the natural balance in the garden or greenhouse.*



Above: *Creating a diverse range of habitats, including a pond, in your garden will encourage beneficial predators.*

## BIOLOGICAL CONTROLS

Nearly every species of plant-feeding insect has another insect that is its predator or parasite. Some pests, such as aphids, are eaten by ladybirds (ladybugs), hoverflies and midge larvae, parasitized by wasps and infested by fungal diseases. Large pest populations are a food larder for many "natural enemies", including carnivorous animals, parasites and diseases.

Biological methods of control use these natural enemies of pest insects to keep their populations under control. It is like having an army of insects and other creatures doing the work for you. Biological controls can be encouraged into the garden by creating a suitable habitat. Ironically, this means that the pests must be present first. They must also be present in sufficient numbers to support a viable population of the beneficial predator. This can be a complex area and the easiest way is to encourage the conditions that will favour a balanced food web to develop. Purchasing beneficials is only generally recommended for use in greenhouses although a few (particularly microbes) are suitable for use outdoors.

## CREATING SUITABLE HABITATS

The easiest way to achieve this is to get a mixture of habitats. The more variety your garden has, the more biodiversity it will support. Ponds, long grass, log piles, and food plants for animals with varied tastes all encourage a stable garden ecosystem where pests are kept at relatively low levels.

Many birds and bats eat insects. Bats need a roosting site, so place a purpose-made bat box on the shady side of a tree. Position the box at least 3m (10ft) high with a clear airspace in front. Night-scented flowers encourage the moths that bats feed upon. This is the key. The predators must be able to live in your garden or they will go and find a more suitable habitat elsewhere.

The longer you garden organically, the more balance will appear in your garden. This is simply because your garden ecosystem begins to stabilize and diversify over time.

Above: *Log piles encourage beneficial predators such as beetles to colonize and take shelter in your garden.*

## BENEFICIAL INSECTS

Predators (those that devour pests directly) and parasitic insects (those whose young hatch inside and devour pests) are often termed "beneficials". Predators include , lacewings and wasps. Parasitic insects (more correctly termed parasitoids) are less well known than predators, but equally effective. They lay their eggs in a pest species. When the eggs hatch, the larvae feed on the pest insect, killing it. The majority of these insects are tiny wasps, although some flies and mites also fall under this category. Learning to recognize beneficial insects is crucial if you want to avoid killing your army of garden helpers.

Above: *Biological controls are a successful way to fight pests. They are mainly used in greenhouses, but others are now becoming available for the open garden. The control insects are released, here from a sachet, in order to attact the pests.*

### BENEFICIAL PREDATORS IN THE GARDEN

There are many beneficial predators that will willingly take up residence in your garden and help to control populations of pests in a natural way.

- Anthocorid bug or red kneed capsid
- Bats
- Birds (robin, blue tit and thrush)
- Centipedes
- Earwigs
- Frogs, toads and newts
- Ground beetle
- Harvestman
- Hedgehogs
- Hoverflies
- Lacewings (adult or larva)
- Ladybirds (ladybugs)
- Mites e.g. *Phytoseiulus*
- Nematodes e.g. *Heterorhabditis*
- Parasitic wasps (*Encarsia* or *Aphidoletes*)
- Slow worm
- Spider on web or wolf spider
- Tachinid flies
- Wasps (solitary and social)

## BIOLOGICAL CONTROLS IN THE GREENHOUSE OR GARDEN

The application of biological controls in the greenhouse or garden involves using predatory insects or other beneficial animals to control commonly occurring pests. Many pests are only a problem because their natural predators are missing from the garden. Introducing a biological control usually results in the rapid control of the pest.

| NAME | PREFERRED TEMPERATURE RANGE | WHAT THEY CONTROL |
|---|---|---|
| *Amblyseus cucumeris* (predatory mite) | 25°C (77°F) | The nymphal forms and adults consume large quantities of immature thrips. |
| *Aphidoletes aphidimyza* (predatory midge larva) | 21°C (70°F); needs 80%+ humidity | Tiny mosquito-like midge larvae that control substantial populations of more than 60 species of aphids. |
| *Cryptolaemus montrouzieri* (predatory beetle) | 20–25°C (68–77°F); needs 70%+ humidity | This ladybird is effective in controlling mealybugs on houseplants and in greenhouses. |
| *Encarsia formosa* (parasitic wasp) | 18–25°C (64–77°F) | Minute, flying parasitic wasps, which lay their eggs inside whitefly scales (the pupa stage) and eat them in two to four weeks |
| *Heterorhabditis megidis* (parasitic nematode) | Minimum soil temperature of 14°C (57°F). If temperature drops below 20°C (68°F), they become less effective. | Patrol the soil to a depth of about 18cm (7in) and quickly take care of the slow-moving grubs, like vine weevil grubs and chafers. Very effective in pots and containers. Soil must be moist. |
| *Metaphycus helvolus* (parasitic wasp) | 20–30°C (68–86°F) | These tiny, black and yellow wasps are effective against several soft-scale species, including brown scale. The females lay their eggs under the body of first- and second-stage scales. The grubs feed on scales and develop into adults within two weeks. Adults also provide control by feeding on non-parasitized scales. *Metaphycus* are most effective in semi-tropical conditions. |
| *Phasmarhabditis hermaphrodita* (parasitic nematode) | Minimum soil temperature of 5°C (40°F) | Useful for slug control. Should be applied during the early growing stages of vulnerable plants. Needs moist soil. |
| *Phytoseiulus persimilis* (predatory mite) | Use once temperature is regularly above 15°C (60°F). Best at 18–25°C (64–77°F); needs 60%+ humidity | Predator mites, slightly larger than the two-spotted mites (also known as red spider mites) upon which they feed. |
| *Steinernema feltiae* (parasitic nematode) | Minimum temperature of 10°C (50°F), although they remain effective when the soil temperature drops below this. | Aggressive predators used to control fungus gnats, mushroom flies and leatherjackets. They can be used on lawns as well as in flower and vegetable gardens, fields, orchards and greenhouses. |

Above: *Ladybirds (ladybugs) are just one of the many beneficial insects that will help to keep garden pests in check.*

### MICROBES

Bacteria, fungi, viruses, protozoans and parasitic nematodes are microorganisms that attack insects. These microscopic hordes are generally effective against very specific pests and present little risk to humans and the environment. Many organic gardeners may well be familiar with a popularly known, microbial-based insecticide known as Bt or *Bacillus thuringiensis*. This commonly available product, which is used to kill many different kinds of moth and butterfly larvae, is a bacterium. It produces a toxin that kills specific caterpillars. The larval pest usually dies within four to seven days. There are many strains of Bt, each type controlling specific pests.

Parasitic nematodes are also very effective against certain pests that live in the soil. However, the nematodes require moist conditions in order to survive and their temperature requirements further limit their use to greenhouses in many cases.

Despite their potential, very few fungi, viruses and protozoa are commercially available because these living organisms are difficult to raise, store and apply. The best way to encourage these willing and tiny helpers into your garden is to maintain a healthy soil that is rich and diverse in terms of the life it contains.

Above: *Providing convenient shelter, such as this lacewing hotel, for beneficial insects can help to increase their numbers.*

# OTHER CONTROL METHODS

*There are many ways of dealing with the different pests that appear in the garden. Some of these methods have been tried and tested for generations, others are individual to the gardener and are often the result of a happy accident. As an organic gardener, you must learn to use as many different tricks as possible to manage the pests in your garden and to protect your plants.*

Above: *Companion plants such as these marigolds confuse or deter pests that would otherwise attack garden plants.*

## GOOD GARDENING PRACTICE

The selection and culture of plants can reduce the potential for pests and diseases. Cultural practices are methods the organic gardener can use to change environmental factors that affect plants and their pest populations. It is essential, therefore, that gardeners know the cultural or growing requirements of each plant. Providing the correct conditions results in a vigorous plant that is less likely to be attacked by pests and diseases and can tolerate some damage.

Left: *Slugs and snails are notorious garden pests that are easily kept at bay using a water trap.*

## ASSESSING THE DAMAGE

When problems do arise, you must decide whether a pest is causing enough damage to warrant control. In other words, you will need to assess how far the problem can be tolerated before action is necessary. Some form of pest damage is inevitable with any crop, but you will need to establish limits. To do this, you will need to take into consideration the amount of damage that can be tolerated, the numbers of an individual pest that can cause significant damage and the plants' stage of development. The health and vigour of the plant can also have a direct bearing on when or if you need to take action. A few holes on a leaf may not require control, but, if most of the leaf has been eaten, the plant may die.

Above: *Compact discs are an unusual and amusing way of scaring away marauding birds from your crops.*

## TAKING ACTION

Monitor your plants to determine when action is necessary. A thorough inspection of the plant allows you to identify a problem before major damage occurs. You should also inspect the plant's entire environment for clues to the problem. Observing and keeping records of weather conditions, for example, can help provide clues to growth patterns and problems.

## TYPES OF CONTROL

Control options can be arranged by their mode of action and their impact on the environment. These methods of control can be grouped from least to highest impact: cultural and mechanical controls and "permitted" chemical controls (soaps, oils and botanical insecticides).

Cultural control includes hand removal of larger pests, the use of screens, barriers, and traps, freezing and crushing. These methods generally have little or no negative effect on the environment and are particularly suitable for smaller gardens.

## COMPANION PLANTING

This is commonly used to protect plants from pest attack. The theory is that the companion plants – flowers growing next to a food crop, for example – disrupt the searching pattern of the pests looking for host plants. They literally smell these hosts but become confused with the more diverse planting style. Separating rows of cabbages, broccoli or other brassicas with rows of onions has always been a popular

combination, possibly because the onion's strong scent confuses cabbage pests. Tomato plants also grow well next to cabbages and seem to deter caterpillars while growing leeks near carrots repels carrot flies.

### SCREENS AND BARRIERS

Any material that is fine enough to keep pests out can be used as a barrier. A variety of screens of different mesh sizes can keep out large insects, birds and rabbits, but they can also prevent pollinating insects from reaching a plant, resulting in lack of fruit. Cardboard and metal collars will prevent cutworms from reaching young transplants. Sticky bands placed on tree trunks trap beetles and soil-hibernating pests. Copper strips are available for slug control. These supposedly react with the slugs' slime to shock them. Sharp particles, such as crushed eggshells, are also used to control slugs.

### TRAPS

Certain insect pests can be monitored by using traps. Sticky coloured traps, pheromone traps and pitfall traps (like beer traps for slugs) can all be used to monitor the occurrence of some pests. Whiteflies and aphids are attracted to bright yellow, and this colour is used for sticky cards upon which they become trapped.

You may want to apply a control and then enclose the plants in netting to keep further infestation from occurring – perhaps putting up netting and then releasing predators.

Traps usually serve as a monitoring system, warning of the presence or increase in undesirable pest numbers. Traps can also be useful in timing control measures by showing the presence of migrating or emerging adults. The control measure can then be introduced at the best time to control the particular pest. Codling moth traps for use in orchards are a good example of this. They are sometimes used to control numbers, but most types are limited in their real effectiveness. Yellow, sticky traps attract whiteflies, aphids, thrips, leafhoppers and other small flying insects. Traps that use pheromones or attractive scents to tantalize adult insects are best used as a way to check presence and numbers. Pitfall traps can be cups or jars placed into the ground filled with yeast and water or beer to trap slugs.

### WATER

A jet of water from a hose washes aphids, spider mites and other small insects from plant foliage. This must be done frequently since it does not kill insects or eggs and it does not prevent some insects from crawling back on to plants.

### INSECTICIDAL SOAPS

These are made from the salts of fatty acids. Fatty acids are components of the fats and oils found in plants and animals. These soaps should not be confused with ordinary cleaning soaps. Insecticidal soaps kill only what they touch and are effective against soft-bodied pests such as aphids, thrips, crawler stage scales, whiteflies, leafhoppers and mites. Insecticidal soaps may cause burning on some plants, particularly those with hairy leaves. Test insecticidal soap on a single leaf if you are unsure – burning will usually occur within 24 hours.

Above: *Birds can be dissuaded from attacking your plants by stretching string and shiny foil over the crops.*

### BOTANICAL INSECTICIDES

Derived from plants, botanical insecticides include pyrethrum, citrus oil extracts and the extract of the neem tree. They act rapidly to stop feeding by insects, although they may not kill the pest for hours or days. There are also disadvantages to the use of botanicals. They must be applied frequently, may be difficult to obtain, and, although generally less toxic than many pesticides, they are still toxic and may harm other beneficial garden residents.

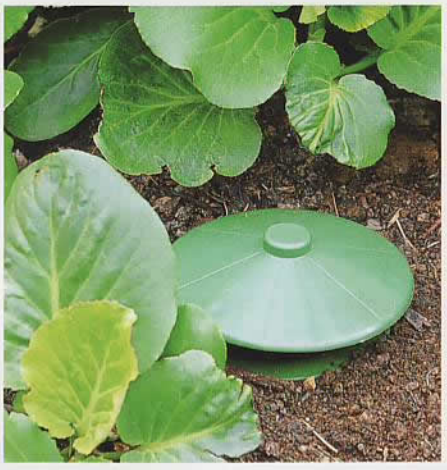
Above: *Sticky traps are another form of pest control in greenhouses. Here, pheromones attract pests to the trap where they get stuck. Other traps consist of sheets of plastic covered with a non-drying glue.*

Above: *Horticultural fleece, which is stretched over developing young plants, can provide a physical barrier against smaller pests such as flying insects.*

### TRAPS, BARRIERS AND DETERRENTS

The prevention of pest and disease attacks is an essential part of organic gardening. Plants that are infected by pests or diseases are weaker specimens that are difficult to treat and never quite recover their former vigour. Many garden pests can be trapped or kept at bay using relatively inexpensive materials and sometimes recycled household items. Put the barriers in place when the plants are young and always ensure that pests are not trapped inside the barrier.

| CONTROL METHOD | HOW IT WORKS |
|---|---|
| **Beer traps and deterrents (granules, copper strips and greasebands)** | Traps are effective ways of both controlling pests, such as slugs, and finding out which ones you actually have. Deterrents are physical barriers over which the pest cannot or will not pass. There are many types and their effectiveness can vary. |
| **Bug nets in the greenhouse** | Greenhouse vents are problematic in terms of pest control in that they allow both pests in and purchased biological controls out. Bug nets are put in place to avoid this happening. |
| **Fleece on frames** | Frames covered in horticultural fleece can be used over outdoor crops to help keep pests out and control the temperature. |
| **Fleece stretched over a crop** | Fleece can be used to create a favourable microclimate around young plants. It also acts as a barrier to airborne pests. On the downside, however, it can also keep out airborne predators from pests that overwinter in the soil. |
| **Fruit nets over fruit** | Fruit nets are especially useful for summer soft fruit crops that can quickly be devastated by birds. |
| **Individual cloches** | Cloches can act as barriers to a wide variety of airborne pests. Any pests that are sealed into this environment may, however, find the perfect environment within which to thrive. |
| **Mesh cages for trees** | Mesh cages are usually used to keep rabbits and hares at bay. They are usually simple constructions formed from three or more stakes driven into the ground with chicken wire (or similar) attached to them. |
| **Rabbit fencing** | A continuous barrier to prevent rabbits entering areas where plants are growing. The base of the wire should be buried below ground level to prevent the rabbits burrowing a passage beneath it. |
| **Bird scarers (e.g. scarecrows)** | Bird scarers have the drawback of a limited lifespan before the birds learn that they are not a real threat. They can, of course, be changed and most bird scarers are only needed on a seasonal basis. |
| **String or wire netting stretched over seedlings (e.g. peas)** | Aerial barriers can protect against bird attack. They may only be needed for the duration of the crop's life or even less. |
| **Traps (sticky, coloured traps used in the greenhouse)** | Sticky traps can provide a certain degree of control against the flying adults of insect pests. However, they are not as effective as they are sometimes thought to be and are, in fact, of more use for showing whether a particular pest is present or not, thereby allowing appropriate control measures to be put in place. |
| **Traps (pheromone)** | Pheromone traps are used to detect the presence of insects. The pheromones attract members of the opposite sex and the appearance of the target species allows you to begin looking for and controlling the young that cause the damage. |
| **Tree guards (spiral)** | Spiral guards are useful for protecting the bark of newly planted trees from rabbits and hares, especially in winter and early spring. These guards expand as the tree develops, but they are best removed completely after about a year. |
| **Tree shelter** | These protect newly planted trees from vertebrate pests and from the worst rigours of the environment by providing a favourable microclimate around them. They naturally degrade under the action of sunlight, but are best removed after two to three years. |
| **Twiggy branches over plants** | Arched over young plants, these can be an effective deterrent to pests such as birds and cats. They do not prevent the migration of beneficial predators to the plants. |



Above: *Slugs and snails can be caught in a trap that is filled with stale beer, or water that has been mixed with yeast.*

Above: *Ring tunnels that are covered in a fine mesh will prevent flying insects from attacking your crops.*

Above: *Plastic netting, stretched over the crop and carefully secured, provides an effective barrier against birds.*

Above: *Old plastic bottles make an ideal barrier to protect young plants from pests. These are cheaper than traditional cloches.*

Above: *Chicken wire, stretched over young plants, will prevent birds from reaching and eating them.*

## ORGANIC PESTICIDES

While most pesticides are not used in organic gardens, some naturally occurring substances can be used to protect your plants from pests and diseases. The pesticides which you are allowed to use in an organic garden should only be applied when necessary and not on a regular basis.

| ORGANIC PESTICIDE | HOW IT WORKS |
|---|---|
| ***Bacillus thuringiensis*** | These are bacterial spores that produce a toxic protein that is useful against caterpillars but will not cause any harm to beneficials. *Bacillus thuringiensis* works quickly, paralysing the caterpillar and so preventing any further damage, although it quickly degrades in sunlight and needs frequent re-application throughout the growing season. |
| **Bordeaux mixture** | A compound containing copper and sulphur used to control various fungal diseases including apple scab and potato blight. It is harmful to fish and livestock, and frequent use can lead to a build up of copper in the soil that can be harmful to worms. |
| **Derris** | A chemical extracted from the roots of the derris and longocarpus plants. It is useful against a variety of insects including aphids, caterpillars, sawflies and plant-eating beetles. It can prove harmful to beneficials, although it is not a threat to bees. |
| **Insecticidal soap** | This is not soap, like the domestic washing soap, but is made from the salts of fatty acids, extracted from plant material. It can be effective against a wide variety of insect pests, although it can damage sensitive plant species. |
| **Plant oils** | Their effectiveness varies but most depend upon coming into contact with the pest itself and suffocating it, although some, like neem tree oil, do appear to have insecticidal properties. |
| **Pyrethrum** | This organic pesticide is extracted from the flower-heads of *Chrysanthemum cinerariifolium* and is especially effective in controlling aphids. However, it does not persist for long and can also cause harm to beneficial insects. |
| **Sulphur** | An effective fungicide against a variety of plant fungi, including powdery mildew, greymould and blackspot. Sulphur can also prove harmful to predatory mites and can cause damage to certain sensitive species. |

Above: *Tree shelters and quills protect trees from rabbits and voles, and also provide an ideal growing environment for the tree.*

Above: *Scarecrows are an attractive method of deterring birds and occasionally large pests away from your vegetable garden. They should be moved around the garden and redressed so that the birds do not get too accustomed to them.*

# THE ORNAMENTAL GARDEN

Unlike the more fleeting nature of crops in the kitchen garden, the plants in the ornamental garden are usually permanent, which means that a stable ecology may be set up very easily. In fact, lawns, shrubs, trees and flower beds can all be adapted to organic culture. The ornamental garden needs flair and imagination, not only in its design and construction, but also in the types of materials it uses; there is little point in creating an organic garden with materials treated with toxic chemicals and wood that was logged from a tropical rainforest.

Left: *A flower garden in the height of summer provides colour and a natural food source for garden insects.*

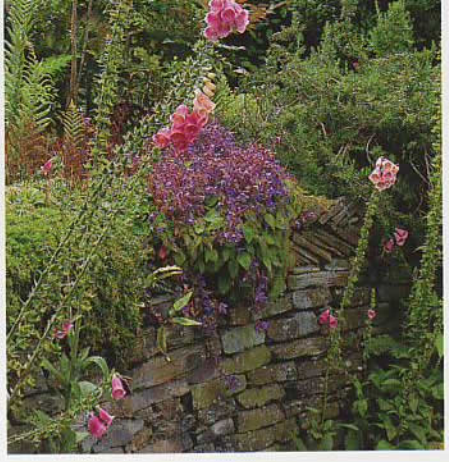
Above: *Flowers are like fuel stations for insects, providing them with nectar in return for pollination.*

Above: *There is an absolutely staggering range of flower forms in nature, many of which are highly ornamental.*

Above: *Careful selection by gardeners has led to the development of many large and showy varieties of flower.*

# THE GARDEN FRAMEWORK

*It would be a great shame if we spent a lot of time and effort creating an organic garden, only to find that we had done so at the expense of another habitat or the wider environment. A truly organic approach to gardening should extend beyond the way we grow the plants and maintain the beds and borders to include all the elements of the garden, from the hardscaping materials to the furniture.*



Above: *A natural dry-stone wall – assembled without mortar – can quickly become colonized with showy flowers.*

## ECOLOGICALLY SOUND MATERIALS

Pictures of logged rainforests, eroded soils and drought-ravaged landscapes are all too familiar. So familiar, in fact, that we run the risk of becoming immune to their shocking truth. Many habitats around the world face increasing pressure from human activities. While there is often little we can do as individuals, we can at least try not to contribute to the demise of such habitats. Rainforests, the source of much of the wood used for garden furniture, are often clear felled, resulting in the loss of much of the biodiversity that they contain.

For this reason, it is important that we use ecologically sound materials. Numerous suppliers claim that they offer ecologically sound products, gathered from sustainable sources. You should check the ecological credentials of the items you buy wherever possible. Buying materials from local sources can help. Always ask who the supplier is, where the materials come from and how their extraction impacts upon the environment. Rocks for alpine gardens, wood for posts and fences, mulch material and potting mixes can all be detrimental to the environment if not carefully sourced.

It is also worth finding out what chemical treatments the material has undergone. Some wood is treated with preservative that may leach out into the soil given time. Potting mixes that are purchased may also contain chemical additives.

Even when products are environmentally sound, it is always worth finding out if the same material (or one that is sufficiently similar) is available from a local source. Transporting materials over great distances, particularly those that are bulky or heavy, involves the use of a considerable amount of fossil fuel. One of the cornerstones of sustainability is to think globally while acting locally. It may even be possible to see the products being made if you do buy from local sources.

Ultimately, of course, the closest source is that which you produce yourself in your own garden. Any organic gardener should, therefore, aim to be as self-sufficient as possible.

### PLANTS SUITABLE FOR COPPICING

Most broadleaved trees can be used for coppicing, although some are more suitable than others as the rate of growth varies so widely. In general, most conifers are not suitable for coppicing because they do not readily re-grow from a stump.

| PLANT SPECIES | SITE | POTENTIAL USES |
|---|---|---|
| **Wattle** (*Acacia*) | Warm dry situations with good drainage. Especially tolerant of low fertility. | Hurdles and barriers (wattlework). Excellent in warmer climates where other weaving species will not prosper. |
| **Gum** (*Eucalyptus*) | Hot dry situations especially where soil is well drained and seasonally dry. | Durable fence posts, stakes and young ornamental growth. |
| **Willow** (*Salix*) | Tolerant of wet situations and heavy soils. The roots are notoriously aggressive and may damage nearby drains or foundations. | Weaving work, building and fencing. In a small garden, dogwood is a good substitute for weaving work. |
| **Hazel** (*Corylus avellana*) | Any garden soil with good drainage and a pH over 6.5. Tolerates frost, shade, and exposure. | Wattle work, weaving, pea and bean sticks. |
| **Sweet chestnut** (*Castanea sativa*) | Light, slightly moist, acid garden soils. Protect from frost and exposure. | Wattlework and fence construction. |
| **Dogwood** (*Cornus*) | Most garden soils but dislikes exposure and can sucker aggressively. | Red, orange or lime-green shoots suitable for basketry and other fine rustic weaving work. |
| **Elder** (*Sambucus*) | An adaptable species that will thrive in a variety of situations. | Twigs are useful for a number of garden projects and the berries and flowers can be used to make wines and cordials. |
| **Honeysuckle** (*Lonicera*) | Likes most soils and thrives with the roots in shade and the topgrowth in full sun. | Stems are a traditional basketry material. |

### USING RECYCLED MATERIALS

Recycling plays an important role in the organic garden. Waste materials from the kitchen and garden are added to the compost heap; plastic bottles can become mini cloches; and old carpet makes a useful protective cover. Old building materials, such as bricks, slabs, quarried stone and wooden railway sleepers (ties), can all be re-used in the garden.

### SUSTAINABLE DESIGN

The more self-sustaining your garden is the better. Gardens that rely heavily upon recycled material – compost, leaf mould and pea sticks, for example – produced within their own confines are naturally self-sustaining. Some external input will always be needed but the garden's long-term success is assured. In short, you will have a sustainable organic garden.

### BIO-ENGINEERING YOUR PLOT

This term describes the use of living material to construct the garden framework. It ensures that you make the most of the natural capabilities of some plant species, such as willow, that have been used for centuries for building and fencing. Other examples include using grass for stabilizing soil on slopes or woody plants for hedging. Living barriers do not rot and are self-sustaining.

## WILLOW WEAVING

**1** *Willow comes in various lengths. The shorter lengths are finest and suited for fine-quality work. This 2.1m (7ft) bundle of "weavers" is the best length for fencing. Thicker uprights are also needed to form the vertical columns to weave around.*

**2** *Place the uprights in the ground about 10–20cm (4–8in) apart, ensuring that they are firmly secured. Use a metal spike to make the holes if the ground is hard. The stakes at each end must be the largest and need to be firmly secured.*

**3** *Groups of four weavers are used together. Place two in the first gap (between the uprights) and the second pair in the next gap along. Take the back pair of weavers in front of the vertical upright, behind the next upright and to the front again.*

**4** *Pick up the other set of weavers and do the same again. Add more weavers as they become thinner and slot these into the uprights to anchor them in. This will give the cross-over effect to the previous weavers.*

**5** *Use successive groups of four weavers and continue to weave. Work from the front in order to ensure that the willow fence is neatly finished. Cut off any stubs as you progress.*

**6** *At the end of the panel, wrap all four weavers round the post and begin weaving in the other direction. Ensure the weave is tight here and avoid making joins in the weave on the end posts.*

**7** *The panels can be solid and used to form a garden boundary. They may also contain spaces, as shown, and act as dividers, while not obstructing the view beyond.*

**8** *The finished willow fence will last for many years, especially if it is adorned with climbers such as ivy. Willow fencing encourages wildlife as well as making an attractive feature.*

# ORNAMENTAL LAWNS

*In spite of the growth in popularity of hard surfaces, such as decking and paving, a well-tended ornamental lawn is still regarded by many as the quintessential feature of a beautiful garden. The lawn provides a safe surface on which children can play as well as an area for relaxing. In the organic garden, the lawn also provides a unique habitat for a wide range of wildlife. There is no reason why you should not have a fully organic lawn that looks pleasing while also contributing to the garden's diversity.*

Above: *A well-manicured lawn is the result of regular care and maintenance. Mowing stripes in the lawn is a finishing touch.*

## WHAT MAKES A GOOD LAWN?

Some gardeners believe that a good lawn is the product of time, patience and effort, which is true of highly manicured lawns. Others believe that an attractive, but low-maintenance, lawn is the ideal. Neither of these lawns is an impossible dream in the organic garden, but consider whether a lawn can withstand the wear and tear it is likely to receive in a small garden. In this case, it might be better to consider an alternative such as paving or gravel.

You should also consider how much time you are willing to spend maintaining the lawn. Short, highly ornamental lawns need more regular maintenance than longer grass areas, but all lawn areas require some degree of maintenance.

## CAN I HAVE AN ORGANIC LAWN?

Lawns, like any community of plants, can be grown quite successfully the organic way. The key to success lies in keeping the grass plants healthy. Lawn grasses are naturally very resilient and competitive plants, well able to withstand a great deal of abuse when they are healthy. Provided they get sufficient light, water, nutrients, air and space, you will be rewarded with an attractive lawn.

### TYPES OF LAWN GRASSES

The grasses below, if present in seed mixes or turf, should prosper in the given conditions. Common names of grasses, while frequently used, are not the same in all countries and the Latin names are given as a definitive reference.

**Coarse-leaved species**
Large-leaved timothy (*Phleum pratense*)
Meadow grass (*Poa pratensis*)
Perennial ryegrass (*Lolium perenne*)
Rough-stalked meadow grass (*Poa trivialis*)
Small-leaved timothy (*Phleum bertolonii*)
Tall fescue (*Festuca arundinacea*)
Wavy hair grass (*Deschampsia flexuosa*)

**Drought-tolerant species**
Chewing's fescue (*Festuca commutata*)
Hard fescue (*Festuca longifolia*)
Meadow grass (*Poa pratensis*)
Red fescue (*Festuca rubra*)
Sheep's fescue (*Festuca tenuifolia*)
Slender creeping red fescue (*F. rubra litoralis*)

**Fine-leaved species**
Browntop bent (*Agrostis tenuis*)
Chewing's fescue (*Festuca commutata*)
Hard fescue (*Festuca longifolia*)
Red fescue (*Festuca rubra*)
Sheep's fescue (*Festuca tenuifolia*)
Slender creeping red fescue
(*F. rubra litoralis*)

**Shade-tolerant species**
Chewing's fescue (*Festuca commutata*)
Hard fescue (*Festuca longifolia*)
Red fescue (*Festuca rubra*)
Wavy hair grass (*Deschampsia flexuosa*)

**Species for damp conditions**
Large-leaved timothy (*Phleum pratense*)
Rough-stalked meadow grass (*Poa trivialis*)
Small-leaved timothy (*Phleum bertolonii*)

**Wear-tolerant species**
Browntop bent (*Agrostis tenuis*)
Hard fescue (*Festuca longifolia*)
Sheep's fescue (*Festuca tenuifolia*)
Tall fescue (*Festuca arundinacea*)

## CARING FOR AN ORGANIC LAWN

Each grass plant occupies just enough space to grow and closely "knits in" with its neighbours. The taller the plants grow, the lower the number of plants in any one space becomes. As they grow taller, their needs increase and the most competitive plants win. Regular cutting results in a dense coverage with short green leaves and a high number of plants in a given area. The more regularly you cut grass, the more vigorously it grows. Irregular cutting means fewer plants in the area. Less frequent removal of the green material at the top of the plants makes the leaf bases white or yellow and also results in a patchy lawn.

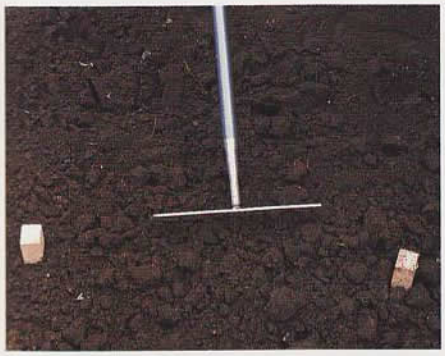
A lawn that is cut regularly will be greener and more attractive than one that is cut more infrequently. In addition, short-cut lawns are an ideal habitat for many garden creatures, particularly birds such as starlings and thrushes. Short grass can even be flower-rich and benefit bees and butterflies.

However, tall grasses favour visiting wildlife and can become an attractive feature in their own right, but they are not ideal for sitting out or for children to play on.

## CHOOSING GRASS PLANTS

Once you know what sort of lawn you want, then you must choose the right grass species for your site and what you want to use it for. Some grass species, such as ryegrass, are hardwearing, while others, like the fescues, are drought-tolerant and need less mowing. Trying to grow the wrong grass species for your garden environment will only work if you go to great lengths to tend it and, even then, it will probably be extremely susceptible to damage. Heavy clay soil that becomes wet in winter will not support a close-mown community of fescues, but would be ideal for a ryegrass and bent mixture.

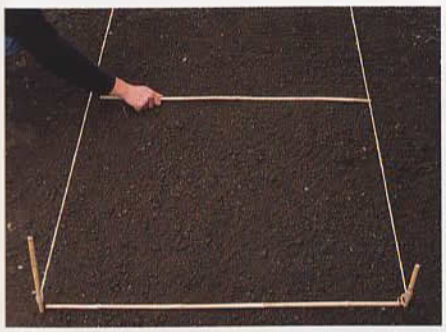
## HOW TO SOW A NEW LAWN



**1** *Dig the ground thoroughly, removing deep-rooted perennial weeds. Rake the soil level. Use pegs marked with lines drawn 5cm (2in) down from the top as a guide, having checked with a spirit (carpenter's) level on a straightedge that the pegs are level.*

**2** *Allow the soil to settle for a week or so, and then consolidate it further by treading it evenly in order to remove large air pockets. The best method by which to do this is to shuffle your feet methodically over the whole area, first in one direction, then at right angles.*

**3** *Rake the consolidated soil in order to produce a fine, crumbly structure that is suitable for sowing seeds. If you can, leave the area for a couple of weeks to allow any weed seeds to germinate. Hoe off the weed seedlings and leave them to die before you apply the grass seed.*



**4** *Use string to divide the area into clearly demarcated strips. The strips should be approximately a metre (yard) wide. Divide the strips into squares with bamboo canes or stakes. Move the canes along the strips as you sow.*

**5** *Use a small container that holds enough seed for a square metre (yard). Make a mark on it if the amount only partly fills the container. Scatter the seeds as evenly as possible with a sweeping motion of the hand.*

**6** *Hire or buy a calibrated granular fertilizer spreader to sow large areas quickly. Check the delivery rates over sheets of paper first and adjust the spreader until the correct amount is being applied per square metre (yard).*

## HOW TO LAY A LAWN WITH TURFS

**1** *Dig and consolidate the soil as for seed. There is no need to leave it for a few weeks to allow weed seeds to germinate; the turf will prevent them from sprouting. Start by laying the turf along a straightedge.*

**2** *Stand on a plank while you lay the next row, as this will distribute your weight. Stagger the joints between rows to create a bond like brickwork. Turf in a long roll will have fewer joints, but these should not align.*

**3** *Tamp down each row of turf to eliminate air pockets with the head of a rake, then roll the plank forwards to lay the next row. Brush sandy soil, or a mixture of peat substitute and sand, into the joints to bind the turfs.*

# LAWN MAINTENANCE

*A rich green lawn is coveted by many gardeners, but a certain amount of maintenance is needed to achieve this. The secret of a healthy and attractive lawn lies in adopting a regular routine. Applying systematic care will also make the lawn relatively easy to maintain. Mowing is the most important and frequent operation carried out, but other practices, including watering, feeding, aerating and top-dressing, will also need to be done to keep your lawn in good condition.*

Above: *Mowing will help to keep your lawn both green and healthy but it must be done frequently for the best results.*

## MOWING

Where mowing is concerned there is a simple rule that you should always remember. The more grass that you remove by mowing, the more rapid its regrowth will be. The cutting height should be higher during late autumn, winter and early spring when little growth is taking place, but may be lowered in the warmer growing season. Raising the cutting height can also alleviate drought-stress and can help lawns stay green during hot dry summers. As a general rule, you should never remove more than a third of the leaf at any one mowing (unless of course you are cutting down an area left deliberately long for wildlife).

Grass can produce 2–3mm (1/12–1/8in) of growth over a 24-hour period in ideal conditions. The single most important factor is that you should mow regularly. Mowing will need to be less frequent when growth is slow, as in periods of dry or cool weather. Remember that lawns may need cutting in mild periods during the winter.

### TURF PROBLEMS

Numerous problems periodically affect turf. The organic approach emphasizes the importance of maintaining strong healthy grass and removing the causes of ill health.

**Organic control of turf diseases**

- Maintain a vigorous growing sward.
- Control moisture to avoid humid surface conditions, e.g. by brushing.
- Ensure free movement of air.
- Regular aeration treatments.
- Reduce thatch.
- Box off clippings where possible.
- Avoid excessive nitrogen combined with cool conditions (in autumn).
- Avoid lime where possible (test water and top-dressings for lime).
- Adopt a balanced fertilizer regime.
- Sterilize loams and top-dressings.

**Organic control of turf weeds**

- Aerate to improve surface drainage and enhance grass vigour.
- Hand-dig persistent weeds.
- Mow and collect clippings regularly.
- Scarify the lawn surface.
- Remove earthworm casts.

## LAWN CLIPPINGS

Grass clippings contain up to 3% nitrogen, 0.7% phosphorus and 2% potassium by dry weight. Returning clippings directly to the grass surface during mowing promotes the recycling of nutrients and "feeds" the lawn. Clippings also add organic matter to the soil, which will retain water, thus making the lawn more drought-resistant and helping to conserve water. On the downside, grass clippings can make turf more susceptible to disease and soil-borne pests and lead to a build up of "thatch" (a mat of partially decomposed grass leaves above the soil surface). Grass clippings should always be removed if they are excessively thick and will restrict future growth. This is especially true if the grass has not been cut regularly enough.

## CONTROLLING THATCH

Thatch is the general term used to describe the layers of organic fibrous material found in turf. It is a perfectly natural component of turf and is desirable to a certain extent because it increases resilience to wear and drought tolerance. Too much thatch, however, can cause an increase in disease, localized dry spots, leaf yellowing, proneness to scalping (during mowing) and a soft spongy surface. It may also affect the tolerance of grass plants to heat, cold and drought.

Top-dressing and avoiding the over-application of nitrogen can help to reduce the build up of thatch, as can liming on acidic soils. Thatch can also be physically removed. This activity is commonly referred to as scarification but is also known as vertical mowing, power-raking or de-thatching. Scarification not only removes thatch, but also removes or controls moss and creeping weeds. It can also help air and

Above: *Grass clippings, leaves and other debris form a thatch at the base of grasses which can stifle them. Remove it with a spring-tine rake. Raking also removes moss.*

Above: *In autumn, rake fallen leaves into piles and scoop them up with a pair of boards. Choose a still day when the leaves are dry to make the job pleasant.*

water to enter the soil. Scarification must only be carried out when the grass is actively growing.

### TURF AERATION

Aeration, put simply, means allowing air to get into the soil. In a lawn, it can improve surface drainage, improve soil air supply and relieve compaction. It also makes the lawn more drought-resistant because of improved, deeper grass root growth. Thatch will be reduced due to the increased microbial activity that is the result of better-aerated soil. Improved drainage leads to a warmer soil that will stimulate root growth and will help release unwanted chemicals and gases from the soil.

You should aerate the turf when the soil is moist, but not wet because it will then damage the soil structure. Aerating the lawn when it is too dry can be difficult if the soil is hard. Small areas can be done by hand, with the traditional garden fork proving very effective for relieving localized compaction.

### ROLLING THE LAWN

Rolling a lawn gives a smooth, flat and level surface, but it is frequently overdone and invariably leads to soil compaction, loss of structure, poor drainage, poor aeration and reduced root growth. It is important never to roll a lawn when it is wet.

#### TOP-DRESSING MATERIALS

Numerous materials can be used as bulky top-dressing and each has its own benefits for both soil and grass plants.

**Charcoal** Sometimes used to improve surface drainage and ventilation.

**Garden compost and leaf mould** Improves the moisture-holding capacity of a rootzone while being relatively sterile. Often best used in mixtures. Homemade compost should be left for sufficient time to decay. Rich in trace elements.

**Sand** Porous and compaction-resistant, sand is used as a component for most top-dressing mixes and on its own.

**Topsoil** Used in "composts" for top-dressing and on its own for fine-turf areas if it contains sufficient sand.

## AERATING THE LAWN

**1** *Poor grass growth could be because the soil is poorly drained. You can aerate the lawn by pushing the prongs of a fork into the ground.*

**2** *Gently brush a soil improver, such as sharp sand or a mixture of soil and sand, into the holes made by the fork.*

## TOP-DRESSING THE LAWN

**1** *Scatter dry topsoil or top-dressing mix evenly over the surface of the lawn using a shovel. As you throw the shovel outwards in a wide arc, twist it through 180° by rotating the handle. This will help you to spread the mix evenly.*

**2** *Using either the flat side of a rake or a stiff broom or besom, work the top-dressing into the surface with short, even strokes. Only apply a top-dressing when the grass is actively growing.*

### BRUSHING

Brushing scatters worm casts, grass clippings and other debris on the surface. It also disperses dew and "dries" the surface of the lawn, making it easier to obtain a clean cut with the mower. Frequent brushing can also act as a mild scarifier, lifting the grass blades ready for mowing. Brushing is also used to "work in" bulky top-dressing into the turf surface. A stiff broom or a besom is the most commonly used tool for brushing turf.

### TOP-DRESSING

This is the application of a bulky material to the surface of the lawn and usually has no or only minor nutritional value. It is carried out to help level the surface or to improve the nature of the soil. It may also help to reduce the build up of thatch.

Top-dressing should be applied when both it and the surface are dry. It must be thoroughly incorporated into the turf using a brush or besom. Top-dress during the growing season so that the grass has a chance to grow through it and never apply so much that it smothers the grass.

Top-dressing is easier to work into the sward if the area has been mown and scarified first. If it is being carried out as part of autumn renovation work you can mow the area closer than normal. Make sure that you use the same type of material each time you apply top-dressing.

## FERTILIZING YOUR LAWN

Organic fertilizers are applied to turf to ensure that there are sufficient nutrients available for healthy, sustained grass growth. The nutrient reserve within the soil is continually being diminished by plant uptake and removal of clippings. Nitrogen is the most important nutrient as it has the most effect upon growth and development. In most situations only nitrogen and potassium will need supplementing by fertilizer application. Most soils have adequate reserves of phosphorus and micronutrients. Organic fertilizers are available as pre-formulated dressings, although fine fertilizers such as fish, blood and bone are quite suitable for early-season application.

Soluble forms of fertilizer (compost teas or worm liquid for instance) should never be applied when grass is not actively growing. The first application of fertilizer in the spring helps to boost grass growth and recovery from winter and quickly improves the appearance of the turf for summer. Closely cut lawns need regular applications every four to six weeks through the growing season. Fertilizer dressing for use in late summer must be low in nitrogen, as an excess will invariably lead to soft growth that is prone to frost damage.

Apply lawn fertilizer evenly over the area to ensure uniform turf grass growth. Poor distribution may lead to scorching in areas that receive too much fertilizer. The best time to apply fertilizer is during a dry interval in a showery weather period when rainfall will wash it into the sward. Water the lawn if there is no rain for 24 hours.

Above: *Feed lawns using an organic fertilizer mix formulated for the season: spring and summer feeds have more nitrogen than autumn ones.*

## WATERING LAWNS

Grass becomes dormant during prolonged dry weather. This may lead to invasion by weed species, but the main concern of most gardeners is that the lawn keeps its colour. Raising the height of cut may reduce this problem, but, in prolonged dry periods, the only real solution is to water. Well-aerated lawns often allow the quickest entry of moisture and lose less water to evaporation. Hand watering may be feasible for smaller areas, but it can be time-consuming. If you live in a drought-prone area, the best option is to choose drought-resistant species.

## TURF GRASS DISEASES

Fungi cause the majority of diseases. The best way of controlling diseases is to keep the grass growing strongly by choosing the right species for the conditions and ensuring that the lawn is well maintained. Not all turf and soil fungi are harmful, however. Many are beneficial, aiding the decomposition of plant materials and organic matter and so releasing nutrients.

## HOW TO REMOVE WEEDS

**1** *Use a special weeding tool or knife to prise out weeds. Push the tool in next to the plant and lever out as you pull. Even deep-rooted plants can be removed like this.*

**2** *Make any necessary lawn repairs. If you have had to lift a lot of weeds growing close together, leaving a bare patch in your lawn, sprinkle grass seeds over the area.*

## HOW TO CREATE A MOWING EDGE

**1** *An edge of bricks or paving slabs prevents flowers smothering the lawn. Mark out the area to be lifted, using the paving as a guide. To keep the edge straight, use a half-moon edger. Lift the grass by slicing it with a spade.*

**2** *Remove enough soil to allow for the depth of the slab or brick and a few blobs of mortar. Make a firm base by compacting gravel or a mixture of sand and gravel. Use a plank of wood to make sure it is level.*

**3** *Bed the edging on mortar for stability. As it will not be taking a heavy weight, just press the slabs on to blobs of mortar and tap level. Lay the slabs evenly and flush with, or very slightly below, the lawn. Check levels.*

## REPAIRING A LAWN

**1** *Lift the area of damaged turf using a large shovel to beyond the point of wear or damage.*

**2** *Cultivate the soil beneath in order to remove compaction or, alternatively, remove all the contaminated soil.*

**3** *Add a layer of new, good-quality topsoil using the shovel.*

**4** *Lightly firm down the topsoil with the back of a rake.*

**5** *Sow grass seed over the newly added soil and gently rake in the seed.*

**6** *Water in the seed and keep the patch moist until the new grass is established.*

### REMOVING MOSS

Moss readily establishes on areas where grass growth is weak. Moss growth is favoured by a moist surface, mowing too close, surface compaction, shade, low soil fertility and excessive pH. Removing moss is palliative and moss soon returns unless the health of the grass is restored. The best solution is to find the cause and remedy it.

### LAWN REPAIRS

There are two methods for repairing turf areas: seeding and turfing. Turf has an instant effect, but seeding is more economical over larger areas. Grass established from seed is usually more hard-wearing.

**Repairing with turves** Mark out the area and use a half moon and turfing iron or a spade to remove the worn/damaged area of turf. Fork over the soil to relieve surface compaction and add a suitable pre-seeding fertilizer. Firm the area by treading. Rake to obtain a tilth. Lay new turves on prepared soil, ensuring all joints are staggered and leaving the turves about 6mm (¼in) proud of the surrounding area to allow for future soil settlement. Top-dress and ensure the area is irrigated when necessary.

**Repairing with seed** Mark out the affected area and break up the soil by forking. Rake to produce a suitable tilth and "top up" soil levels if need be. Consolidate the surface by treading and apply a suitable pre-seeding fertilizer. Rake to a tilth and sow the seed in two (or more) directions. Rake in the seed, ensuring the area is level with the surrounding turf. Firm by rolling, if required.

**Overseeding** This method is used to thicken an existing lawn. Seed is scattered over the lawn, where the seed will then germinate, grow and fill-in the turf surface. Overseeding can be done by hand, broadcasting and scratching in the seed. When overseeding grassy areas, lower seed rates are used than those for new lawns. When soil conditions are dry, ensure that the seed is covered and in contact with the soil underneath. Keep the soil moist until the seed germinates and establishes.

**Repairing damaged edges** Mark out and lift an area of turf around the damaged edge. Fork over the soil in order to prepare a tilth and relieve surface compaction. Incorporate a suitable pre-seeding fertilizer and firm the area by treading. Rake to obtain a suitable tilth. Re-lay the turf with the damaged edge innermost. Top-dress the newly laid turves, working the top-dressing into the joints. Pay particular attention to the damaged zone. The top-dressing should ideally have a small quantity of seed mixed into it. Alternatively, the area may be overseeded once the turf is laid and top-dressing applied. Ensure the area is irrigated when necessary.

Above: *Insert a half-moon edging tool into the soil. Lever forwards to form a gulley with one vertical side against the lawn and one curved side against the border.*

# WOODY PLANTS

*Woody plants maintain permanent living structures above ground. They are unique in that their stems repeatedly thicken and strengthen, as is easily seen in the familiar growth rings in wood. Woody plants take many forms: they can be small ground-hugging shrubs or forest giants, and both the largest and oldest living things on our planet today are woody plants. They are the backbone of many gardens, providing height and structure as well as a feeling of permanence.*

Above: *Woody plants, such as this flowering quince (*Chaenomeles*), often have very decorative and colourful flowers.*

## BUYING WOODY PLANTS

Woody plants may be bought bare-rooted or rootballed, or in containers. All plants should be vigorous, healthy and suitable for the site conditions and intended use. Check that bare-rooted specimens are properly wrapped so as to prevent their roots drying out and ensure that trees and shrubs are free from any obvious pest or disease.

## PREPARING THE GROUND

Organic matter is best incorporated across the whole area as a mulch after planting. This encourages the development of a healthy root system. Apply across the whole site during digging if the soil is sandy.

Adding fertilizer is only generally recommended when analysis reveals the soil to be deficient in particular nutrients. Woody plants set up mutually beneficial relationships with soil fungi and gain much of their nutrients as a result of natural nutrient cycles. Often, the best floral displays occur on soils of low fertility, making fertilizer unnecessary.

The key to woody plant growth usually lies in applying organic mulch on an annual basis. Leaf mould is arguably the best substance to use, but well-rotted compost or manure is almost equally useful. An application of bonemeal or similar organic base dressing before mulch is applied can prove to be beneficial when shrubs are newly planted.

## PLANTING OUT BARE-ROOTED OR ROOTBALLED TREES

The soil should ideally be moist and friable, not frozen or excessively dry or waterlogged. Bare-rooted or root-balled specimens are usually planted during the dormant season. For deciduous broad-leaved species, this is in winter. An early planting results in better establishment in the following season, and often makes the

## PLANTING A SHRUB

**1** *Never plant a shrub that is stressed. Before you start planting, check that the plant has been watered. If not, give it a thorough soaking, preferably the night before planting. If this is not possible, ensure that the shrub is watered at least an hour before you plant. This allows the water to be absorbed thoroughly by the potting mix and will help the plant to establish.*

**2** *If the soil has not been recently prepared, fork it over, removing any weeds. Add a slow-release fertilizer, such as bonemeal, wearing rubber or vinyl gloves if required, and fork this in.*

**3** *Dig a hole wider than the rootball. Put the plant in the hole and check it is deep enough by placing a stick across the top of the pot. It should align with the top of the soil. Adjust the depth of the hole accordingly.*

**4** *Remove the plant from its pot, taking care not to disturb the rootball. If it is in a plastic bag, cut away the bag rather than trying to pull it off. Place the shrub in the hole and draw the earth around it. Firm the soil down with the heel of your boot and water in well.*

**5** *Finally, mulch all around the shrub, covering the soil with an 8–10cm (3–4in) layer of bark or a similar material. This will not only help to preserve moisture but will also help to prevent any weed seeds from germinating.*

## PLANTING A CLIMBER

**1** *Dig over the proposed site, loosening the soil and removing any weeds. If the ground has not recently been prepared, work some well-rotted organic material into the soil to improve soil texture and fertility.*

**2** *Add a general or specialist shrub fertilizer, if necessary, to the soil at the dose recommended on the packet. Work into the soil around the planting area with a fork. A slow-release organic fertilizer is best.*

**3** *Water the plant in the pot. Dig a hole that is much wider than the rootball. The hole should be at least 30cm (12in) from the wall or fence. The free-standing canes will be angled towards the wall or fence.*

**4** *Stand the plant in its hole and place a cane across the hole to check that it is at the same level. Take the plant from the pot or cut the bag away. Holding the plant steady, fill in the soil. Firm as you go with your hands.*

**5** *Train the stems up individual canes. Tie in with string or plastic ties. Even twining plants or plants with tendrils will need this help. Spread them out, so that they will ultimately cover the whole of their support.*

**6** *Water the climber thoroughly. Put a layer of mulch around the plant to help preserve the moisture and prevent weed growth. Do not pile mulch up against the stems of the climber, however.*

plants more resistant to spring drought. Evergreen specimens establish more readily if planted during early autumn or late spring in conditions in which enough moisture is available for rapid root growth.

Mark out the positions of the plants and dig each pit, allowing ample space to accommodate the roots, rootball or container size. This is usually a quarter to half the diameter again of the rootball. Take care not to smear the sides of a pit dug in heavy soil as this will effectively cause it to fill up with water during the wetter months, resulting in root dieback, subsequent shoot dieback and in extreme cases, the death of the whole plant.

Remove protection from the roots and place the tree into the hole. Prune any damaged tissue with a sharp knife or secateurs (hand pruners). Position the plant in the pit with roots well spread. Where trees require staking, the stake should be hammered into the ground before planting the tree to avoid damaging the roots. Position the stake on the side from which the wind most commonly blows.

### PLANTING OUT CONTAINER-GROWN PLANTS

Container-grown specimens may be planted throughout the year, provided that the ground is sufficiently moist and adequate water supplies are available and used to irrigate the newly planted area. Other site-related stresses, such as high wind and hot conditions, may also have to be minimized where plants are planted outside of the optimum winter period. Preparation of the planting pit, and staking, are the same as for bare-rooted or rootballed trees, but the positioning of the rootball and treatment of the roots differs slightly. Remove the tree from the container and lightly shake out the rootball over the hole of excavated soil. Check the root collar area for girdling roots. These are roots that spiral around and may eventually damage the developing stem. Where present sever these cleanly with a knife and remove carefully out of the rootball. Tease out the lower roots using a fork. Place the rootball in the hole so that the roots are spread out and the surface of the potting mix is level with the ground. Tease out the circling roots at the edges of the rootball with a fork or by hand especially where plants are pot bound. Fill in and firm, staking where required.

Immediately after planting, remove any damaged, diseased or untidy growth. Do not remove excessive amounts of top growth, however, as this will reduce the plant's ability to produce food.

### STAKING TREES AND SHRUBS

Large shrubs and trees larger than about 1.2m (4ft) may require staking. Low stakes are now recommended as they allow the top growth to move in a circular motion. This motion encourages rapid lower-stem thickening and the development of fibrous root systems that are essential for quick establishment and support of the plant.

### PROTECTING NEWLY PLANTED SPECIMENS

Plants unused to cold or hot drying winds may suffer from drought stress. Cold drying winds may damage foliage, buds and branch tips, as well as the bark of thin-barked tree species unused to such exposure. Tree shelters protect trees from adverse conditions, providing an extremely suitable environment for the rapid growth and development of the tree. They are also useful in protecting plants from voles, rabbits and sometimes deer attack. They are usually designed to last three to five years before the material starts to degrade under the action of sunlight. Shrub shelters are similar in most respects to those for trees but are generally shorter.

### STAKING A STANDARD ROSE

**1** *For a standard shrub, make sure you use a strong stake. It should be of a rot-resistant wood. Firmly place the stake in the planting hole, knocking it into the soil so that it cannot move.*

**2** *Plant the shrub, pushing the rootball up against the stake, so that the stem and stake are approximately 8–10cm (3–4in) apart.*

**3** *Firm the soil down around the plant with the heel of your boot.*

**4** *Although you can use string, a proper rose or tree tie provides the best support. Fix the lower one 15cm (6in) above the soil.*

**5** *Fix the second tie near to the top of the stake, but just below the head of the standard shrub.*

**6** *Water the ground around the plant thoroughly and mulch with chipped bark or a similar material.*

Spiral guards, designed to protect larger trees from rabbits, can act as tree shelters for smaller plants. When used on larger trees, they are designed to expand as the stem diameter increases, thereby not constricting growth. Open-mesh guards, which are mesh rolls supported with two or more canes or stakes, provide alternative rabbit protection.

Re-firm roots of all newly planted trees and shrubs after wind or frost, using the heel of your boot, to exclude air pockets around the roots.

Irrigation should only be applied on very dry soils during the first year of establishment. Water is best applied only when absolutely necessary using a sprinkler to thoroughly drench the soil.

All shrub and tree bases should be kept weed-free during the first year. Mulching may help to achieve this, but some hand weeding may be necessary.

### RENOVATING OLDER SHRUBS

Shrubs that become overgrown look unsightly and will often have a poor display of flowers. Many shrubs can, however, be rejuvenated by pruning. In certain cases the pruning programme can be staggered over a period of two or more years. Deciduous species, such as lilacs (*Syringa*), may be pruned after flowering, or more commonly during the dormant season. Evergreen shrubs, such as *Viburnum tinus*, are best treated in mid-spring. Remove all weak spindly growth and any badly placed branches or crossing stems. Remove stems to leave a balanced framework by cutting them back to around 30–45cm (12–18in), depending on the species and its vigour. Mulch using leaf mould or compost to 5–10cm (2–4in) in depth. Ensure that the plant is never short of water in the summer.

The following season the shrub will have produced a mass of new shoots. These should be thinned as necessary. After renovation, all shrubs should be pruned according to their normal requirements.

### RENOVATING HEDGES

If hedges become overgrown or too wide through neglect or incorrect maintenance, they may respond to drastic pruning methods. The method is similar to that which is carried out on shrubs. Instead of cutting hard back to the base, however, only one side of the hedge is pruned back hard to the main stems of the hedge plants.

Left: *Flowering trees such as these cherries (*Prunus*) can provide a welcome and refreshing splash of spring-time colour.*

One side of the hedge is left alone so there is enough foliage area left to stimulate new growth and recovery on the pruned side. This can also prove useful in providing cover for wildlife, especially nesting birds.

The process is repeated on the other side of the hedge the following year or, perhaps, two years later. Evergreen subjects (but not conifers) should be pruned in this way during early to mid-spring and deciduous subjects when they are dormant in late winter.

Feed using an organic mulch, such as farmyard manure, and water during the following season to ensure that the hedge survives such drastic pruning. This technique can be very successful for many evergreen plants as well as most deciduous plants.

### RENOVATING WOODY CLIMBERS

Climbers that have not been pruned or trained properly often degenerate into a tangled mass of woody stems which look unsightly and give poor foliar or floral displays. Hard pruning will often rejuvenate the plant. In most cases, the plant will tolerate close pruning in early spring to within 30–60cm (12–24in) of the ground or its main framework of branches. Plants in poor health may not survive this treatment, in which case you may need to carry out the work over a period of two or more years.

Water the base of the plant well and apply bulky organic material. New growth must be trained and pruned according to the species. New growth can initially be trained as if it were a newly planted climber.

### PROVIDING PROTECTION

**1** *Many shrubs need some winter protection. This shrub is in a pot but the same principles can be applied to free-standing shrubs. Insert a number of canes around the plant. Cut a piece of horticultural fleece, hessian (burlap) or bubble plastic to size, allowing room for overlap. Wrap around the plant, using a double layer for very tender plants.*

**2** *Tie the protective cover around the pot or lightly around the shrub if it is in the ground. Horticultural fleece can be tied at the top because moisture can penetrate, but, if you are using bubble plastic, then leave it open for ventilation and watering.*

# FLOWERS FOR BEDS AND BORDERS

*Flowers are an essential part of the ornamental garden and there can be few sights that can rival a flower border at the height of summer. Understanding the lifecycles and horticultural needs of these plants is essential if you are to use them to their best effect in flower beds and borders. This section looks at planting and caring for herbaceous perennials, bulbs and annuals.*

Above: *Few sights in the ornamental garden can rival that of a flower border in full bloom in mid-summer.*

## HERBACEOUS PLANTS

The strict definition of a herbaceous plant is one that dies down to or near to ground level each year in order to avoid harsh and extreme weather conditions. In the garden this includes herbaceous perennials as well as grasses – which may not actually die down but never exceed a certain height – and bulbs.

Herbaceous perennials are non-woody plants that live for more than one year. They usually grow, flower and set seed before dying down to ground level in the autumn. They remain there until the next season when the cycle begins again. Herbaceous perennials may form sizeable clumps which are best divided every three to five years to maintain vigour and promote flowering.

Ornamental grasses contrast superbly with broad-leaved plants and narrow-leaved forms and are ideally suited for creating "dry" gardens.

The maintenance requirements for the vast majority of these plants are the same and they form the backbone of the ornamental garden by providing colour which, if planned properly, may benefit the garden all year round.

**Planting out** Herbaceous plants may be planted in either autumn or spring. The advantage of autumn planting is usually noticed on drier soils as the plants establish and are potentially more drought resistant. Those planted on heavier soils may benefit from spring planting, as heavy soils may be wet and cold – conditions that may cause the newly planted specimen to rot. Grasses are planted in the same way as "true" herbaceous plants. Bulb planting is different and is dealt with separately.

Pot-grown specimens should be watered at least an hour before planting. The ground should be dug and manured before being levelled ready for planting. A base dressing of bonemeal or fish, blood and bone may also be applied. Plant only when the soil is moist, but not waterlogged or frozen. Dig a pit larger than the rootball and ensure that the plant is well firmed, taking care not to compact the soil when it is returned around the rootball. Care should be taken immediately after to ensure that slugs and snails do not damage the crowns. Set traps and barriers around them to avoid this.

**Thinning** Removing weak shoots allows the plant to divert its energy into the remaining shoots, which will be sturdier and produce larger flowers. Thinning is carried out when the plant has reached one-quarter to one third of its eventual height and is useful for plants such as as delphiniums, phlox and Michaelmas daisies.

**Stopping** This is the removal of the growing tip of a stem in order to encourage the side shoots to develop. The tips may be

## HOW TO PLANT PERENNIALS

**1** *Always prepare the soil first. Dig it deeply, remove weeds, and incorporate a fertilizer and well-rotted compost if the soil is impoverished. Most perennials are sold in pots, so arrange them to create pleasing associations.*

**2** *Water thoroughly at least an hour before knocking the plant from its pot, then dig a hole. If the rootball is congested, tease out a few roots first. Work methodically from the back of the border or from one end.*

**3** *Carefully firm the soil around the roots with the heel of your boot. This helps to remove any large pockets of air.*

**4** *It is important that you always remember to water thoroughly after planting and keep the new plants well watered in dry weather for the first few months.*

pinched out when the plant has attained a third of its ultimate height. This encourages the buds on the leaf axils to develop and leads to more flowers being produced, although these will be smaller than if the one terminal bud had been allowed to flower. This technique is successful for a range of plants including *Helenium*, *Rudbeckia*, *Dahlia* and *Chrysanthemum*.

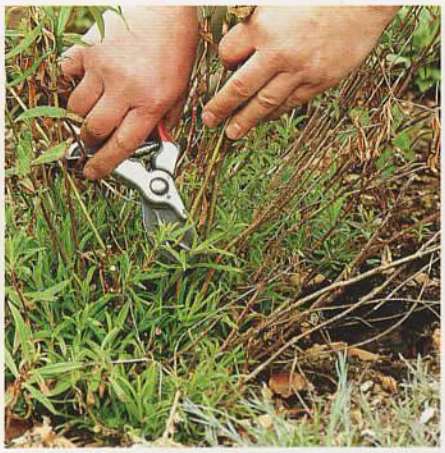
**Dead-heading** Unless the plant produces decorative seed heads or seed is to be collected for propagation purposes, it is often best to remove all flowers as they begin to fade. Further side shoots will then often develop and the flowering period will be extended. Notable exceptions to this are those plants that produce seed heads that are valuable food sources for overwintering birds. Examples of this include teasels, *Echinops* and many of the ornamental grasses.

**Cutting back** Some shrubby perennials (often referred to as sub-shrubs), such as *Chrysanthemum*, *Phygelius* and *Penstemon*, benefit from being pruned annually in early spring. This is especially true of sub-shrubs that are somewhat tender. The older twiggy and unproductive growth is cut hard back in order to promote the growth of new shoots that will flower in summer and autumn.

**Feeding** Few perennials require more than an annual fertilizer application if initial soil preparation has been thorough and included the addition of bulky organic matter. An organic fertilizer, such as bonemeal or fish, blood and bone, may be added to the soil in spring, preferably after rain.

Above: *When dead-heading, snip off the flowers cleanly where they join the stem. Cut back to the first set of leaves if a whole head of flowers has to be removed.*

## CUTTING BACK



**1** *Some herbaceous plants remain green throughout winter. Cut back to sound growth, removing dead and leggy material.*

**2** *Here, the old stems have been cut off so that they are level with the emerging growth, so as not to damage it.*

Bulky organic material, such as leaf mould or compost, applied in spring before shoot growth is also beneficial. Care must be taken not to apply this too thickly and not to cover the crowns of plants resting at the soil surface as these may rot off.

**Renovating** Herbaceous perennial plants should be lifted, divided and replanted every three to five years. Some fast-growing and vigorous plants, such as *Ajuga* and *Stachys*, may need to be divided every year. Herbaceous plants can become woody towards the centre and may lose vigour.

Lifting the plants for dividing will not only rejuvenate them but also allows for other border maintenance operations to be carried out. The site can be cleared of any weeds and organic matter such as compost or manure dug into the border. The process of division is beneficial to the whole border. In addition, it keeps the plant healthy and will prevent the over-vigorous growth of fast-growing species. Lifting and dividing is normally done while the plants are dormant in late autumn or early spring.

**Transplanting** Most perennials can be transplanted relatively easily. This should be done during the dormant season, which is usually in autumn or early spring. Some plants dislike cold wet conditions and these should be moved once the soil has warmed sufficiently to encourage growth. This is particularly true for any plants that are not fully hardy. Some plants that are relatively long-lived, such as peonies, resent being disturbed and will take two or more years to establish again after transplanting.

**Plant replacement** If possible, all planted areas should be designed to contain plants that have similar life spans and respond to rejuvenation techniques. Some species are relatively short lived and will die out before others within a bed. It is possible to rejuvenate beds on a set cycle, say every three to four years, and avoid gaps appearing in the periods between.

Plant losses can occur in severe winters when those that are normally regarded as hardy are exposed to very low temperatures. Half-hardy or tender perennials are even more susceptible. Some perennials are probably best lifted and stored over winter until the worst weather has passed, when they can be planted out again.

Above: *Lightly dig over the soil around the plants, removing any weeds. Avoid digging around plants such as asters which have shallow roots.*

## ANNUALS AND BIENNIALS

As the name suggests, annuals are plants that grow, set seed and die, completing their lifecycle within one growing season. Some garden annuals may actually be perennials in nature, but are treated as annuals for ease of cultivation. Many half-hardy and summer bedding annuals fall into this category. Almost all spend a maximum of one calendar year in the ground before dying off.

Biennials are similar to annuals as they flower once and die, but differ in that they grow and establish in the first season before resting in a similar manner to herbaceous perennials over winter. They grow, flower and die the following season. Some plants that are grown as biennials (especially as bedding) are perennials. They are treated as biennials, however, because they tend to weaken during their second year and are therefore better re-started in order to maintain vigorous plants.

Annuals are used as displays in their own right or as small groupings of colour among more established plantings. Groups of annuals strategically placed together in, for example, containers can have a greater visual impact than if they were spread throughout the garden. Many annuals, especially those with composite flower heads, attract beneficial insect species into the garden and some are used as companion planting for vegetable crops. Annuals can also be a useful infill in new borders as they are easily removed or thinned out later when the perennials have grown and become established.

**Planting annuals, biennials and tender perennials** Hardy annuals can be sown *in situ* and then thinned. Some may self-seed freely through borders. If annuals are to be grown in pots or trays prior to planting, the planting is much the same as for herbaceous plants. Always ensure that the risk of frost has passed before planting out tender specimens and that these plants are acclimatized thoroughly beforehand.

## PLANTING ANNUALS

**1** *Remove the plants from the pack. If they are attached to each other, try not to tear off too many roots when removing. Dig a hole wider and slightly deeper than the rootball.*

**2** *Fill in the hole around the plant with soil and gently firm down with your hands. Water the plant with a watering can fitted with a fine rose.*

## SPLITTING CONGESTED PLANTS

**1** *Some perennials need splitting every few years to keep them flourishing. In spring, lift the whole of the clump from the ground.*

**2** *Clean the ground thoroughly, removing any weeds, particularly perennial ones that have appeared since the border was last dug.*

**3** *Incorporate some well-rotted organic material such as farmyard manure in order to rejuvenate the soil.*

**4** *Remove the earth from the plant and divide. Use the new growth around the edge, and discard the woody centre.*

**5** *Replant some of the divisions, making certain that the roots are well spread out. Firm them in and then water.*

**6** *Keep the plants watered until they have re-established themselves. They will soon fill out the gaps in the border.*

## SOWING SEED IN OPEN GROUND

**1** *Dig over the ground and break it down into a fine tilth using a rake. Do not work the soil when wet or it will become compacted.*

**2** *Using a garden line as a guide, draw out a shallow drill. Use the corner of a hoe, a stick or a trowel.*

**3** *If the soil is very dry, water the drill using a watering can and leave to drain. It should not be muddy for sowing.*

**4** *Identify the row with a clearly labelled marker. This is important because when the row is backfilled it will be impossible to see where the seed is until it germinates.*

**5** *Sow the seed thinly by hand along the length of the drill. Sowing thinly will reduce the amount of thinning that is required at a later stage.*

**6** *Rake the soil back over the drill and lightly tamp it down with the back of the rake. When the seedlings emerge, thin them out in order to prevent overcrowding.*

---

Many hardy annuals thrive in poorer soils, and are undemanding and easy to grow. Dry banks are ideal for a whole range of species including poppies and nasturtiums, both of which flower more abundantly on slightly poorer soils.

The only "pruning" required for annual plants is dead-heading to promote new shoot and flower development, or stopping to promote side shoot development and multiple flower production as opposed to large single flowers.

### BULBS, CORMS AND TUBERS

These rest below the surface and are modified buds, stems or roots. They emerge, often for only a short time to grow and flower, before retreating back down underground to escape harsh weather conditions.

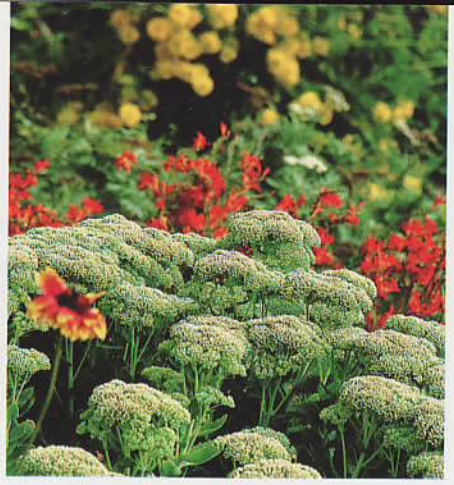
**Planting and maintenance** Bulbs, corms and tubers can be lifted during their dormant period and transported and stored easily. Generally speaking, bulbs are planted in a hole that has been dug to about two to three times their length deep. Bulbs have a base plate, which is where the roots appear. This must always be placed in the hole roots down and should be in contact with the soil in the base of the hole. Placing fine sand in the base will ensure this. The top of the bulb (the neck) should always point upwards. Fill the hole firmly once the bulb is in the hole. After this the bulbs need little care and attention, although tall varieties may need staking and all should be dead-headed after flowering.

Above: *The rule is that bulbs should be planted at a depth of three times their own size. Exceptions include nerines, crinums and some lilies, which prefer to be planted with the top of the bulb at soil level.*

Above: *Dig a large hole, according to the requirements of the individual bulbs or corms. These gladioli corms are placed, base down and nose up, about 10cm (4in) apart. Gladioli corms need to be lifted in autumn.*

# BEDS AND BORDERS

*Whether you are creating a flower border from scratch or updating an existing design, there are a number of important factors that you will need to consider before you start planting the scheme. Begin by looking very carefully at the site and its conditions. This initial planning and preparation will help you in your choice of plants. Hardiness and suitability to the soil type, as well as the aspect of the site, are also factors that will determine which plants will thrive.*



Above: *Flowers are not only decorative, but will also encourage pollinators and other insects into your garden.*

## PLANNING AND SITING

Ideally, the bed or border should be positioned in a sunny site away from the shade of trees or buildings unless you intend to plant a border with shade-loving species. A hedge, wall or fence can provide valuable protection for your plants, and will create a warm microclimate for more tender plants. A sheltered spot will also extend the planting season. These structures may also provide a backdrop for climbers.

When you begin planning the border, ask yourself what you hope to achieve. Borders that are to be viewed from a distance will benefit from larger groupings of each plant type. Larger specimens can also appear very striking from further away. These can be used as character plants and provide a recurring theme through your border.

Borders may have a particular theme. They may be planted with fruiting shrubs, plants to create a "tropical" look or fragrant plants such as philadelphus and lavender for rich summer fragrance. Colour also provides interesting themes. A golden border of yellow flowers in association with plants that have variegated or yellow leaves is striking. Remember that you can leave gaps in the planting for seasonal features

Left: *Herbaceous borders are easy to create and maintain, and can provide year-round interest if they are properly planned.*

Above: *Combining strong colours such as orange and blue can produce striking planting associations.*

such as bedding plants and bulbs. Decide what look you would like to achieve before buying any plants.

## SEASONAL CONSIDERATIONS

Ask yourself when you want the border to look its best. Perhaps you would like a bright display of bulbs in spring followed by a colourful selection of annuals and bedding plants in summer. Alternatively, you may want to plan for a bed or border that provides year-round interest, in which case you will need to consider a selection of hardy shrubs or perennials that are appropriate for your garden conditions.

Make a list of all the plants that you would like to include and when they will look their best. Many plants have more than one season. For example, shrubs such as *Viburnum opulus* flower in early summer and have bright red berries in autumn. If you intend to use winter-stem shrubs such as *Cornus alba*, then choose varieties with interesting foliage, such as the golden form 'Aurea'.

## COLOUR CONTRASTS

Once you have your list of desired plants, consider their colours. Contrasting colours can look effective. Try plants that have blue, purple or pink flowers, and choose as many examples of these as you can find with bronze foliage. A much brighter combination would call for hot vibrant colours such as yellow, orange and red.

Cottage gardens throw all caution to the wind, including a riot of contrasting and clashing colours to provide unexpected and beautiful combinations of hue and form. Alternatively, you might prefer a monochrome scheme, using flowers of one colour – white or cream, say, offset by a display of green foliage.

## FOLIAR AND TEXTURAL EFFECTS

Placing plants with contrasting foliage next to each other can create great interest in a border. This is also true where evergreens are used in conjunction with winter-stem colour. *Cornus sibirica*, for example, has striking red stems in winter and is best shown off against a carpet of weed-suppressing variegated ivy. Textural contrasts can also be striking. For example, the bold leaf forms of plants such as *Rheum* contrast well with the more feathery forms of astilbes and *Aruncus* in summer.

## THREE-DIMENSIONAL STRUCTURE

When you plan out a border on paper, it can sometimes be difficult to envisage just how it will look when it is established and growing. In order to get a better idea of the final result, it can be helpful to draw a sketch relief of the border. This should always be done as a projection into the future, based upon the lifespan of the plant. This will be the following year in the case of herbaceous plants but may be five years or more in the case of shrub beds.

## PLANTING OUT A PERENNIAL BED

**1** *If the bed was dug in the autumn, winter weather should have broken down the soil. In spring, rake over the soil and remove any weeds that have reappeared.*

**2** *Although well-rotted organic material should have been added at the time of digging, a sprinkling of bonemeal will ensure the plants get off to a good start.*

**3** *Draw a grid on a plan and then mark out a scaled-up version on the bed, using sand or potting mix. Alternatively, use string between canes to mark out the plan.*

**4** *Using your planting plan and grid as a guide, lay out the plants, still in their pots, on the ground. Stand back, try to envisage the border as it will be, and make any necessary adjustments.*

**5** *Dig a hole and, with the plant still in its pot, check that the depth and width is right. Adjust if necessary. Remove the plant from the pot and place in the planting hole. Fill in the hole with soil and then firm the plant in.*

**6** *When the bed is completely planted, water in all the plants. They should be kept watered until they have become established, especially throughout dry periods.*

**7** *Go over the border with a fork, or use a rake if there is room. This will loosen any compacted areas, as well as level the soil.*

**8** *Cover the soil between the plants with a layer of mulch like composted bark to keep weeds down and preserve moisture.*

**9** *Mark each plant with a label. The finished border should need little attention, apart from removing the odd weed.*

### PLANTING GROUPS

When designing and planning your border, always remember to set out and plant the herbaceous plants in groups of three, five, seven or nine. In this way, you can create a more natural and informal effect because this approach does not show the rigid lines or geometric shapes that often appear when you plant even numbers of plants.

Larger planting groups than this need not adhere to this number rule because an overall random effect is created by the shape of the drift alone. Larger shrubs, such as *Deutzia* or *Buddleja*, can make stand-alone specimens. Smaller shrubs, such as rosemary or potentillas, may well have greater impact if they are positioned in groups.

### CREATING BORDERS WITH HERBACEOUS PLANTS

The popularity of herbaceous plants has meant that they are used in a wide variety of different situations in the garden. However, they are primarily used in the herbaceous border where they can be shown to great effect. Three important categories of this kind of border are usually recognized.

**One-sided borders** These were extremely popular in Victorian and Edwardian gardens and are the very essence of the English "gardenesque" style. The design usually involves creating a border along one side of a pathway, with the plants arranged in order of ascending height from the path edge. The border is usually positioned in front of a solid backdrop beyond which the eye cannot see.

The backdrop may be living, such as a hedge, or man-made, taking the form of a wall or fence. These beds, while pretty, are often limited by their lack of perspective. The relative proximity of the backdrop often draws attention away from the nearer plants and destroys any illusion of distance. This drawback can be rectified by planting mainly red-flowered plants at one end of the border, gradually changing to blue-flowered plants at the other end. This makes the border seem longer than it actually is. Such schemes are only really effective, however, in borders that are 10m (35ft) or more in length.

**Island beds** These differ from one-sided borders in that the plants can be viewed from all sides by walking around the whole bed. This kind of planting does not have a backdrop and relies, therefore, on the strategic placement of groups of large plants in the centre of the feature. Island borders allow the onlooker to view the plants from a number of different angles, thus enhancing the interest of the border as a whole.

**Mixed borders** These designs use many types of plant, including trees, shrubs, herbaceous plants, annuals and bulbs. In a mixed border, one group of plants should complement and enhance the other. For example, the trees provide the shelter and backdrop for the shrubs and flowers in a woodland garden. Rock gardens can also be regarded as mixed borders, with a rich (if diminutive) array of dwarf trees, creeping shrubs and ground-hugging herbaceous plants and bulbs.

## ROSE BEDS

A well-tended, healthy and pest-free rose bed has long been, and indeed continues to be, the desire of many gardeners. However, roses can be at risk from pests and diseases. This risk is increased when too many roses are grown in one bed. Most modern cultivars are also too highly bred to resist the range of diseases that can affect them, having been chosen for flower size rather than disease immunity. Choose old-fashioned varieties or modern cultivars that offer resistance to disease.

Most rose pests are common garden pests that are easily controlled by natural predators. The trick with roses is to indulge them with plenty of colourful companion planting, especially daisy-type plants – *Argyranthemum* is ideal – which will encourage those beneficial insects into your garden. It can yield wonderful results and makes the bed even more colourful. Old-fashioned roses need less work in general than modern cultivars and are often more suitable for pollinating insects like bees.

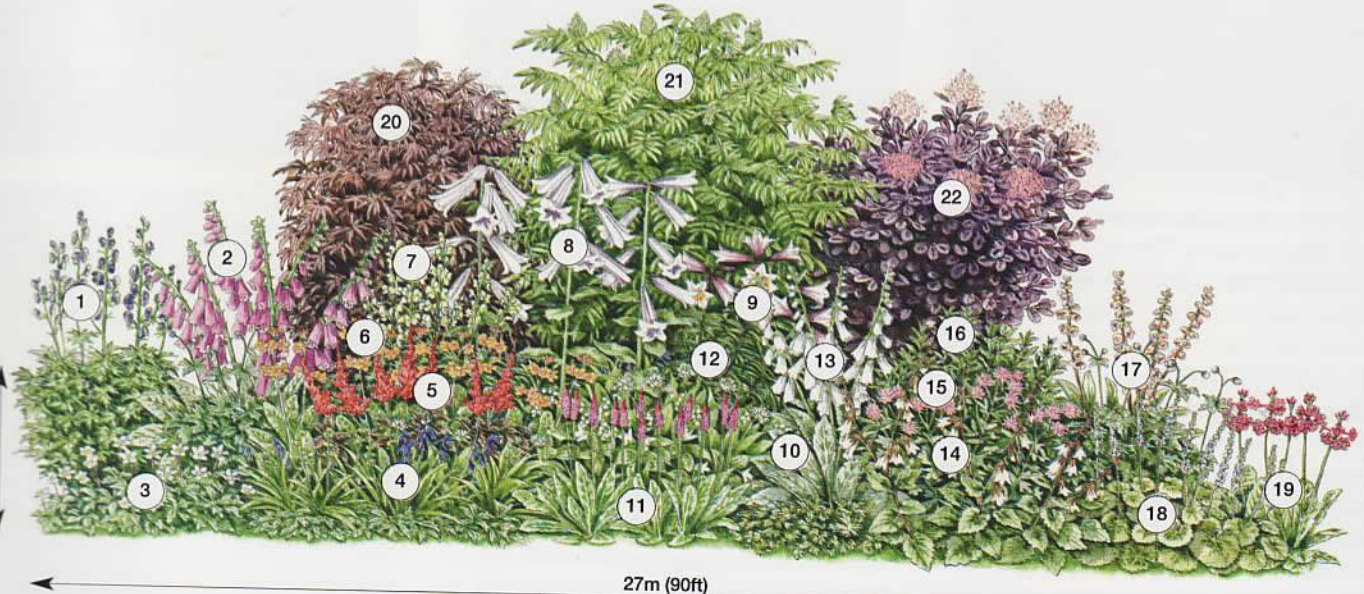
## GROUNDCOVER PLANTING

This is a way of exploiting the competitive abilities of plants that grow by spreading sideways and smothering their neighbours. An obvious example of a plant type that is good for this is turf grass, but many herbaceous and shrubby species are also able to fulfil this function. These include conifers, roses, heathers, and both broadleaved evergreens and deciduous

### A PARTLY SHADED BORDER

*A shady spot in the garden can provide the right growing conditions for a dazzling array of flowers. This mixed border in heavy shade is shown in summer to late autumn.*

1 *Aconitum napellus* (poisonous)
2 *Digitalis purpurea* (poisonous)
3 *Anemone sylvestris*
4 *Hyacinthoides non-scripta*
5 *Astilbe* 'Aphrodite'
6 *Primula bulleyana*
7 *Aconitum napellus vulgare* 'Albidum' (poisonous)
8 *Cardiocrinum giganteum*
9 *Lilium regale*
10 *Convallaria majalis*
11 *Primula vialii*
12 *Anemone nemorosa*
13 *Digitalis purpurea* var. *alba* (poisonous)
14 *Campanula alliariifolia*
15 *Aquilegia vulgaris stellata* 'Nora Barlow'
16 *Aster novi-belgii*
17 *Digitalis ferruginea* (poisonous)
18 *Galax urceolata*
19 *Primula japonica* 'Millers' Crimson'
20 *Acer*
21 *Mahonia* 'Charity'
22 *Cotinus coggygria*



plants. Their main characteristic is a close, compact and low-growing form that suppresses the underlying weeds. The same effect can, of course, be achieved by planting closely. This method is especially useful with herbaceous plants that grow up quickly and suppress the weeds below. No groundcover will suppress all weeds, however, and you may have to weed among them while they become established.

There are numerous groundcover roses available that offer a colourful carpet of flowers. If you opt for roses as a groundcover, you should be aware that some are covered with thorns and it can be difficult to weed between them. Mulching the bed following planting can help to suppress weeds until the plants achieve full cover. All groundcover can take two to three years (or more) to become fully established and so should be considered as a long-term, labour-saving feature.

## BORDER MAINTENANCE

It is possible to plan a border to be low maintenance, but there is no such thing as a maintenance-free border. Decide how much time you can spend caring for the border and choose your plants accordingly. A close planting, particularly one that uses ground-covering shrubs or closely planted herbaceous plants, will certainly cut down on the weeding as can mulching the border regularly. Any border will need at least one seasonal tidy up in late winter. Shrub beds are also best mulched at this time before bulbs and other flowers have fully emerged. Choose shrubs that will grow into the space available and avoid very vigorous varieties or ones that need pruning on a regular basis. Even large herbaceous borders need not be too difficult to maintain. Delay your winter clear up for as long as possible and choose species that do not need staking. Do not worry if the plants grow among each other, it will just add to the effect. The less labour a border needs, the less disturbance there will be to the wildlife it contains.

## TIDYING UP

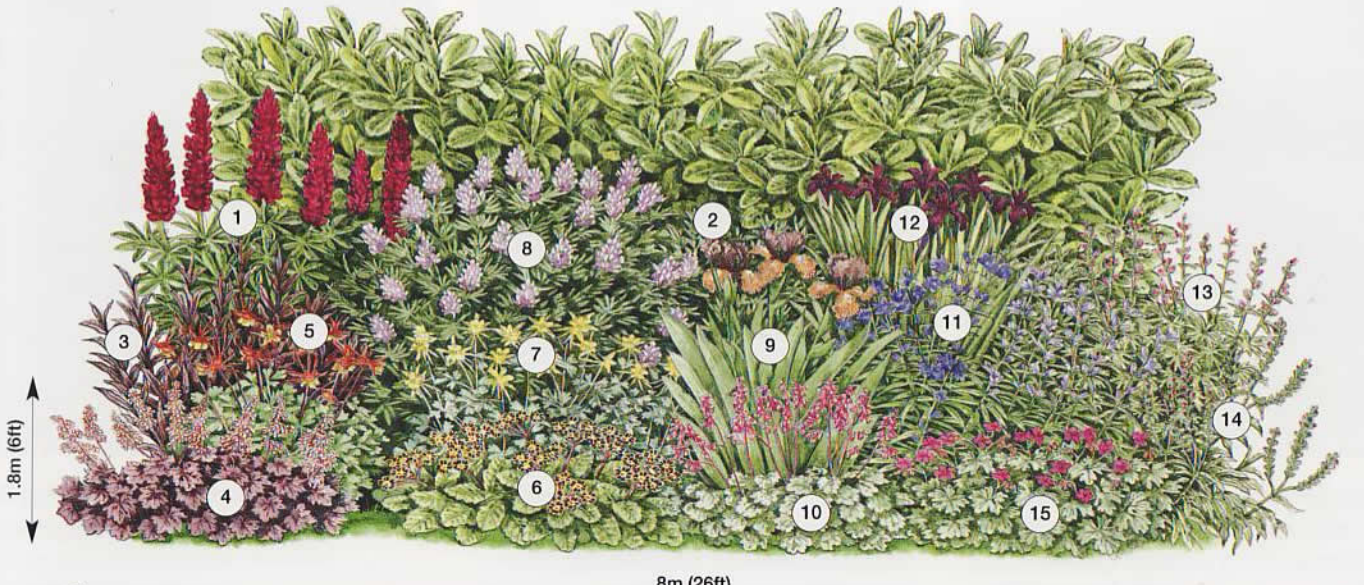
**1** *Some edging plants spread out over the grass, possibly killing it or creating bald patches, as has this poached egg plant (*Limnanthes douglasii*).*

**2** *If the plant is an annual and has finished flowering, it can be removed. Otherwise, just cut back the part that is encroaching on the grass.*

### A SPRING BORDER FOR AN OPEN, SUNNY SITE

*A sunny spot can provide the ideal conditions for a wide range of showy blooms in the early part of the year. The plants in this border prefer a neutral to slightly alkaline soil.*

1 *Lupinus* 'The Page'
2 *Aster novi-belgii* 'Fellowship'
3 *Lobelia* 'Bees Flame'
4 *Heuchera micrantha* 'Palace Purple'
5 *Aquilegia skinneri*
6 *Primula* 'Gold Lace'
7 *Aquilegia chrysantha* 'Yellow Queen'
8 *Lupinus arboreus* 'Mauve Queen'
9 *Iris* 'Blue Eyed Brunette'
10 *Heuchera* 'Leuchtkäfer'
11 *Campanula latifolia* 'Brantwood' (deep blue) and *C. latifolia* 'Gloaming' (light blue)
12 *Iris chrysographes*
13 *Sidalcea* 'Party Girl'
14 *Physostegia virginiana* 'Vivid'
15 *Geranium macrorrhizum* 'Ingwersen's Variety'



# CONTAINERS

*These are an attractive feature in any garden and are very useful when there is no soil at all for planting, as is the case with patios and roof gardens. They are also easy to maintain. There are many types of container available, which means that you can create a theme of your own choice: Mediterranean or perhaps lush and tropical in style. You can also plant up seasonal containers to create different effects through the year or you can change the style from year to year.*

Above: *A wooden barrel makes an attractive container in which to grow a profusion of plants.*

## TYPES OF CONTAINER

Always choose containers that fit in with the general garden style and with each other. Terracotta and wooden planters are easy to fit into almost any garden scheme, but shiny metal containers may be more difficult to place. Hanging baskets usually take the form of a basket of wire, but they can also be made of wicker. This is lined with a permeable material such as wool, hay, coir matting or even conifer cuttings. You can buy purpose-made lining material which is made from recycled materials or you can make your own. Hanging baskets are an excellent way of covering a wall or post and can even increase the growing space in your greenhouse. They are best planted with a selection of trailing plants (placed around the edge of the basket) and upright types (placed in the centre). They are extremely prone to drying out and should be watered at least once a day and even twice in hot dry conditions. Window boxes should be treated in a similar way to hanging baskets.

The size of a container will influence the kind of plant that you can grow. Any container must be at least 15–20cm (6–8in) deep, although most plants will be happier in a deeper one than this. Be wary of putting a small plant in a very large pot, as this can lead to very wet potting mix that the plant will not want to root into. Large pots with arrangements of several plants are ideal and much easier to look after than several smaller pots.

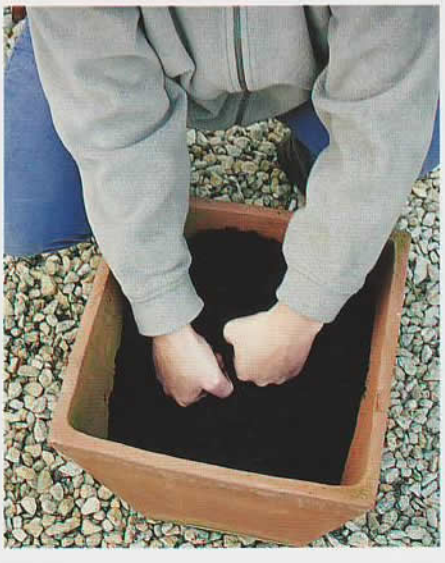
## MATERIALS AND FINISHES

Containers are available in a range of different materials and finishes. Glass fibre and resin containers are extremely strong and lightweight but they tend to be expensive because they are hand-made. They are available as extremely realistic stone-look containers, but can also be found in almost any other finish, including wood and glazed ceramic. Plastic containers are very cheap, lightweight and often last a long time. The finish on some may be poor, but they are very easy to paint and customize. Metal containers are available as pots, "manger-style" window boxes or hanging baskets. There are many different designs and the best quality ones have a properly lacquered finish.

## PLANTING A CONTAINER

**1** *The materials you need include a suitable container, your choice of plants (in this case, the central plant is a striking cordyline), some stones to place at the bottom of the container for drainage and potting mix.*

**2** *Cover the bottom of the container with small stones or some pieces of tile or pottery, so that water can drain freely from the container.*



**3** *Partly fill the container with a good-quality potting mix.*

Above: *Hanging baskets can help to provide colour and interest at eye-level throughout the year.*

Above: *Using a watering can is one of the easiest ways to keep the soil moist. It allows you to deliver the right amount of water.*

Above: *You can create a stunning display with a range of different containers, including an old wheelbarrow.*

Stone and terracotta pots offset the shades of flowers and foliage beautifully. The main problem with terracotta is that it is water permeable and requires more frequent watering than plastic, resin or metal pots. Both stone and terracotta containers can be very heavy, so plant them up *in situ*. Look out for frost-resistant types that will not crack in winter. Glazed ceramic pots need less watering than plain terracotta pots, and can be chosen in almost any colour to suit the theme of the garden.

Wooden or wicker planters have a very natural look and can easily be home-made. Oak, cedar and chestnut are the best woods to use because they do not need preservative and planed wood – of any type – can easily be painted. Wicker is an excellent material for making hanging baskets, while wood can be used for window boxes. Wicker or wooden planters benefit from being lined with plastic or a non-permeable paint. The paint can be plastic resin or bitumen based, but make sure that it does not contain fungicides or preservative. Alternatively, plastic sheeting can be stapled firmly inside the pot. Wooden and wicker pots should be raised off the ground slightly to prevent the base rotting. There are many different designs, ranging from half-barrels to wheelbarrows. However, take care with wooden items for outdoor use because many of them have been chemically treated. A wide variety of recycled objects can be used as containers. An old boot, bucket or watering can, painted if you wish, can all be used.

## DRAINAGE

All containers must have drainage holes in the base. To ensure that the potting mix drains freely, place a layer of gravel – about 4cm (1½in) deep for most pots – over the base of the pot before putting in the mix. Terracotta and stone pots may need as

**4** *Scoop out a hole in the potting mix and insert the plant, positioning it so that the top of the rootball will be level with the surface of the potting mix.*

**5** *Place any extra plants around the edge of the main plant. Add more potting mix in order to fill in any gaps, and firm down. Water the container thoroughly.*

**6** *The plants will soon grow away and fill out the container to create a stunning year-round feature.*

much as one-fifth of their total depth filled with gravel to help protect them from frost damage. Standing pots on bricks or purpose-made "feet" also helps them to drain freely.

### ORGANIC POTTING MIX

The best potting mixes contain sufficient air space to allow the roots to breathe, while retaining enough water and nutrients to support plant growth. Potting mix must also be heavy enough to support the weight of the top growth of the plant if it is to remain upright. You can buy a general-purpose potting mix, although some gardeners prefer to mix their own.

Potting mix can be loam-based or soilless. Loam-based potting mix is a "heavy-weighted" mix that provides good anchorage for tall or heavy specimens. It also holds on well to nutrients. It is ideal for plants that will stay in containers for several years or more as it will not degrade or become structureless.

Soilless potting mixes do not contain loam. They have the advantage of being free-draining and relatively lightweight, although some grit or sand is usually added to give them weight. Coir-based potting mixes are made with a natural fibre that is a by-product of the coconut-growing trade. It has been hailed as a peat substitute and is equally good in containers. However, it is expensive and can be difficult to re-wet once dry. Composted fine bark is cheap and readily available. There have been some advances in its use in recent years and it has even been suggested that bark-based potting mix increases a plant's resistance to pest and disease attack.

### PLANTING A HANGING BASKET

**1** *Line the hanging basket with a suitable organic material. Conifer branches are an ideal material, as is shown here.*

**2** *Fill the lined basket with a suitable soilless organic potting mix to about one-third of its depth.*

**3** *Position the plants first to see how they will look. Fill in the spaces between the plants with more potting mix.*

**4** *Any gaps between the plants can be filled with small bulbs or bedding in order to provide a riot of spring colour.*

### MAKING ORGANIC POTTING MIX

You can make your own potting mix with ingredients such as well-rotted compost, leaf mould and worm compost; loamy garden soil; and clean, coarse sand or fine grit. The organic matter and loam should be thoroughly sieved. A slow-acting, balanced fertilizer may also be added along with ground limestone to bring the mixture's pH to around 6.5 which is suitable for the majority of plants. Containers for seasonal displays such as bedding will not need loam.

### PLANTS FOR CONTAINERS

Fruit, herbs and even vegetables can all be grown in containers, as well as a wide range of ornamental plants. A flowering shrub such as an azalea can act as a focal point and enliven a shadier part of the garden. Pots of fresh herbs and salad crops can provide a welcome addition to summer meals and a window box can even be used as a miniature wildlife garden. Seasonal bedding can transform a patio into a riot of colour and be changed regularly to reflect the seasons. Containers also enable you to grow a range of plants that would not otherwise grow in your soil. For example, if your garden soil is alkaline, you can still enjoy the spring and summer delights of acid-loving rhododendrons, blue poppies (*Meconopsis*) and Himalayan primulas.

### CARE AND MAINTENANCE

There are a number of tasks that you will need to perform in order to keep your container plants in peak condition.

**Watering** Knowing when and how much water a plant needs is one of the most important aspects of container gardening. Often a look at the surface of the potting mix may give the impression that it is dry. If you dig down with your finger, however, you quickly discover moist potting mix. If the mix feels wet, then do not water it.

**Feeding** Container plants need more fertilizer than plants grown in the open garden because frequent watering washes out the nutrients. For the best results, start feeding container plants six to eight weeks after planting. Use a liquid tea, worm liquid or a purchased soluble food such as seaweed extract or liquid manure every two to three weeks. Apply fish emulsion or garden compost once or twice a season to add trace elements to the mix. Do not add more than the recommended rate of any fertilizer as too much can harm plant roots.

## PLANTING A WINDOW BOX

**1** *Assemble all the necessary materials. These include the window box, crocks, a good organic potting mix and the plants. If the box is light, assemble it on the ground. If not, then assemble it in position.*

**2** *Holes in the bottom are essential to allow good drainage. Stop the potting mix from being washed out by placing crocks over these. If very good drainage is needed, then a layer of gravel can also be added.*

**3** *Partially fill the box with potting mix, gently tapping the sides to make sure that no air gaps remain. Never over-firm soiless potting mixes as they will become waterlogged and airless, and the plants will suffer.*

**4** *Place the plants in position and check these positions before finally planting. Make sure that they are planted in the potting mix at the same depth that they were in their pots or trays. Plant them fairly close for an instant effect.*

**5** *A selection of bulbs makes a useful additional display for the window box. The bulbs can be planted in among the main plants and are best planted in groups of three so that they give a fuller display. Water the basket once it is planted.*

**6** *Window boxes that are planted for seasonal display will quickly use up all the available nutrients. This is less of a problem with baskets planted for winter interest, such as this, but summer boxes will need regular feeding.*

**Monitoring plant health** Containers are best placed where they will receive maximum sunlight and good ventilation. During periods of high temperatures and bright sunshine, many containers may benefit from shade during the hottest part of the day. Shelter plants from severe rain, hail and wind storms. Also watch out for and control insect pests.

**Pinch pruning** When young, the growth of many ornamentals is readily shaped by the pinching out of young shoots. Many specimens treated in this way yield impressive results. This pinching out, or stopping as it is sometimes called, stimulates the development of side shoots and, if carried out regularly, results in dense bushy growth. The selective use of this method of pruning allows for considerable freedom in the shaping of plants.

### MAKING ORGANIC POTTING MIX

Mixing your own organic potting mix is relatively easy. You can use a combination of a variety of materials, including loam, leaf mould, garden compost and worm compost.

| INGREDIENTS | RATIO BY VOLUME | ADDITIONAL INFORMATION |
|---|---|---|
| Loam : Leaf mould : Garden compost | 1 : 1 : 1 | A basic mix that is well drained, fertile and suited for longer-term plantings. |
| Leaf mould : Worm compost | 3 : 1 | Very nutrient rich. Add extra grit for better drainage. Best for short-term pots of vegetables, herbs and flowers. |
| Loam : Manure : Leaf mould | 3 : 1 : 1 | A rich mix for heavy feeding plants such as pot-grown tomatoes and peppers. |
| Leaf mould : Loam | 1 : 1 | Ideal for long-term plantings such as trees and shrubs. Use acidic loam for lime-haters. |
| Loam : Leaf mould or Coir | 1 : 1 | Enrich with 225g (8oz) seaweed meal; 110g (4oz) bonemeal; 85g (3oz) hoof and horn; 55g (2oz) ground limestone per 30 litres (63 pints) base potting mix. |

# THE WILDLIFE GARDEN

Wildlife gardening involves providing food, shelter and a habitat for creatures as well as relying on native plants that are suited to the climate and soils in the locality. A single plant species may directly and indirectly serve species of insects, invertebrates, fungi, and other organisms, which in turn become a meal for larger wildlife such as birds. In time you will have a functioning ecosystem on your doorstep. In fact, creating a garden of this kind can help break up the "grass desert" responsible for reducing the variety of birds, insects and other wildlife.

Left: *Wildlife gardens use plants, such as this fennel (*Foeniculum vulgare*), for their ability to attract insects.*

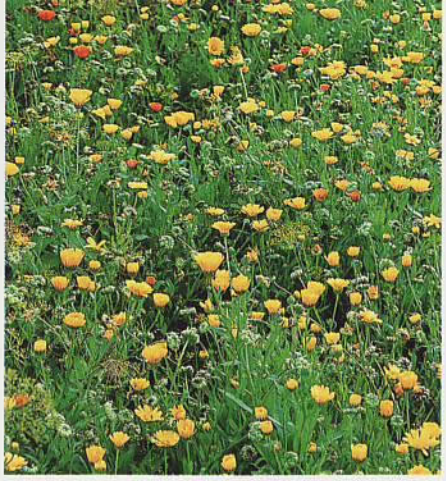
Above: *Garden wildlife can be both pretty and, in the case of ladybirds (ladybugs), useful for controlling aphids.*

Above: *Flowers such as sweet peas (*Lathyrus odoratus*) encourage pollinators and beneficial insects into your garden.*

Above: *Colourful fruits such as these rosehips provide much-needed food for garden wildlife such as birds.*

# WHAT IS A WILDLIFE GARDEN?

*The organic garden can provide a welcome refuge for a wide range of wildlife, from birds and butterflies to creatures such as frogs and hedgehogs. The basic requirements for any visitor to the garden are food, water and shelter. You may also want to consider organizing some, or all, of your planting schemes around species that will attract a diversity of fascinating wildlife.*



Above: *Wildlife gardens such as this grassland area can be attractive as well as providing useful habitats.*

## WHAT ARE THE BENEFITS OF A WILDLIFE GARDEN?

Domestic gardens cover a huge area around our towns, cities and urban fringes. This is a potentially fantastic resource for an otherwise denuded habitat. Keeping your garden free of harmful chemicals gives you a head start in attracting wildlife and, with a little planning, you can create a habitat that will welcome a diverse range of creatures. The visitors in turn will repay you by acting as predators, helping to control the level of problem-causing pests in your garden. Knowing that your patch, no matter what its size, is providing a haven for wildlife will give you a closer connection with the natural world. Just to be able to enjoy watching birds feeding can lift the spirits and improve your sense of wellbeing.

Encouraging natural cycles in your garden will promote biodiversity. The more soil life there is, the more insects will come to feed on it. Birds will come to feed on the insects, as will amphibians and mammals. In this way, food webs will gradually recover in the absence of pesticides.

Making your own garden compost, instead of using peat, for instance, prevents damage to a fragile habitat that cannot be re-created. Collecting rainwater and using this in the garden will reduce the consumption of mains water. Huge amounts of energy are wasted on cleaning and transporting this precious resource and it is often extracted from rivers at levels that threaten the local wildlife. The careful gardener can encourage the creation of wildlife habitats in their own backyard and prevent habitat destruction somewhere else.

## CREATING THE RIGHT HABITAT

Much of the wildlife that thrives in a garden does so under the care of a gardener who is not unduly tidy. The best wildlife gardens

### A WILDLIFE GARDEN

*A well-designed wildlife garden will provide food and shelter for a host of different creatures.*

Above: *Looking at natural habitats such as woodlands can provide inspiration for your own garden.*

leave room for decay. This approach – and it is one that is good for organic gardens in general – involves piling up old logs and autumn leaves in a quiet shady corner to create a home for insects and hibernating hedgehogs. Do not confuse this with making leaf mould pits; these stay in place and gradually rot down. Log piles can also be overplanted with ivy to enhance both their appearance and attractiveness to insects such as stag beetles.

Consider planting native trees, shrubs and flowers so that native creatures will have a familiar food source or nesting site. Plant as many suitable flowers as possible to attract bees, butterflies and other insects that will enhance your wildlife garden. Many beneficial species are attracted to a garden that is effectively a feeding station for them. For the larger visitors, such as small mammals and birds, you can plant flowering and berrying trees and shrubs.

Ponds provide a rich habitat for a variety of wildlife. Many familiar creatures, such as frogs, toads, newts and dragonflies, depend upon ponds to breed. Many urban gardens have become havens for these creatures. Even a small pool will provide somewhere that birds and other visitors can come to drink. If you have no space for a pond, try introducing a suitable container that can be utilized as a drinking or bathing area for birds, mammals and even insects.

Just leaving the lawn uncut for a few weeks in mid-summer will give many of the plants you do not normally see the opportunity to flower. An area of longer grass also benefits butterflies, moths and many other insect species by providing food and shelter. Many of these insects will fall prey to larger garden occupants such as songbirds and hedgehogs, so diversifying and enhancing the food web in the garden.

The barriers and structures in your garden also provide very useful habitats. Hedges are a sanctuary for all sorts of wildlife, where they can breed, feed and take shelter. These hedges are easy to maintain, as they should only be cut once in the winter to avoid interfering with spring and summer nesting birds. Cutting is done on alternate sides in alternate winters. If one side is cut this winter, then the opposite side is cut the next. This ensures that only one side is clipped before the growing season. The unclipped side flowers and provides nectar and fruit for wildlife. Dry-stone walls are another garden feature that can provide homes for hibernating amphibians, lizards, insects and bees and are best left undisturbed throughout the winter.

Above: *Recycling organic material through composting reduces the need to use substances such as peat.*

If you are lucky enough to have a few trees in your garden, you could try to re-create a woodland habitat. Larger gardens may actually contain a small area of woodland but most are more likely to have a shady patch under a few trees. Choose plants that mimic a woodland floor: bluebells, anemones and sorrel are just a few of the handsome plants that will thrive in these conditions. Planting a few understorey shrubs (those that grow below the trees) such as holly and hazel will complete the effect and may well tempt the shyer woodland birds into your garden.

## WILDLIFE CORRIDORS

A wildlife garden is often likened to an oasis in an urban desert. Gardens are the only chance of cover that many creatures have to migrate between larger blocks of suitable habitat such as parks or a greenbelt. If these important habitats become totally isolated then they begin to lose much of their diversity. Town gardens play a vital role in protecting the health of the wider urban habitat, while rural gardens play a similar role in areas denuded by intensive farming. Try putting up a few bird or bat nest boxes and providing nesting areas for insects and mammals. The greater the year-round diversity, the more useful your garden will be.

# WOODLAND GARDENS

*Woodland can be one of the most interesting and diverse natural habitats. Those with smaller gardens may think that such a feature would be too large for them to create. However, even a few trees in the corner of the garden can provide ample opportunity for the creation of a small wooded area and provide a rich and diverse habitat for a range of visiting wildlife. Try to select native trees or species that have nectar-rich flowers or berries.*

Above: *Woodlands are home to many of our favourite garden flowers such as these primroses (*Primula vulgaris*).*

## WHAT IS WOODLAND?

Woodland is a very variable habitat and its exact character will mostly depend upon the prevailing climate. It is often a more open environment than that of a forest, having clearings, glades, pools and streams that break up the monotony of tree cover.

Large trees such as oak (*Quercus*), beech (*Fagus*) or plane (*Platanus*) are known as the woodland canopy. Beneath the canopy are smaller trees such as holly (*Ilex*) and hazel (*Corylus*), known as understorey species. They are often shade-tolerant trees, but grow best under gaps in the canopy. Beneath this, a shrubby layer develops in more open woodland, possibly consisting of bushes such as hawthorn (*Crataegus*) and elder (*Sambucus*).

The floor of the woodland is called the herb layer. The plants that live here tend to be seasonal, taking advantage of early spring sunshine to grow and flower, although some, such as mosses and ferns, grow through the summer. It is also where all seedlings grow and is mulched each year with the falling leaves of the trees.

## CREATING A WOODED AREA

Gardeners who have a few trees (even if they do not provide a continuous canopy) can easily make a small woodland area. Visit some woods in your area to gain some inspiration and emulate natural growth if possible. Think how the existing tree cover can be linked, maybe by planting more canopy species and some understorey trees.

Woodland environments are often havens for plants and animals, with many containing an enormous diversity of species. This is most pronounced where there is a "mosaic" of open ground and trees. This is because it increases the "marginal areas" – the point between woodland and more open habitat. The places where two habitats meet are always the most diverse. Layered woodland (one with canopy, understorey, scrub and ground herbs) is beneficial for wildlife as it provides ample feeding and shelter for a range of creatures. Any additional planting should always be aimed at achieving or maintaining this layered structure and providing the highest number of habitats.

You can think of woodland as a collection of diverse habitats. Even those that have only a few types of tree are capable of supporting a great number of species that live on or within these trees. Oak trees in Britain, for instance, are known to provide homes for over 400 insect and other invertebrate species. This does not mean, however, that simply planting an oak tree in your organic garden will guarantee all 400 will appear at once. If you aim to create a woodland that is similar to others in your area, then species will be able to migrate from these to the one in your garden.

You may need to provide additional help for wildlife if it is to establish successfully in the woodland area. Nesting boxes, log piles, rocks and a long grass area linked to your pond can all help to encourage wildlife to use your planting as a habitat. Make sure that you include plants that provide food and be prepared to give additional sustenance, especially in the winter for non-hibernating foragers such as blue tits and other woodland birds. As the woodland develops, so will the diversity it contains. Let nature do its work and give a helping hand from time to time.

## PLANTING WOODLAND FLOWERS

In most deciduous woodland, the ground is a riot of colour from late winter until early summer as showy woodland species grow, flower and set seed before the leaves in the canopy cast too much shade. As a consequence, most "woodland gardens" are at their best from late winter to early summer. The edges and clearings provide the chance for later colour, of course, but

Left: *Shady and partly shaded wooded areas can provide the perfect habitat for a host of creatures.*

Above: *Foxgloves (*Digitalis*) thrive in shady woodland corners and are very easy to grow from seed.*

Above: *Bluebells (*Hyacinthoides*) naturally grow and flower in the spring before the trees shade them.*

some of the showiest species are to be found among the spring flowers. Choose species that grow in your own area, where possible, because these will be of most benefit to wildlife.

Primroses (*Primula vulgaris*), bluebells (*Hyacinthoides*), snowdrops (*Galanthus*) and wake robin (*Trillium grandiflorum*) are all guaranteed to give a good display, especially at a time when there are fewer colours in the rest of the ornamental garden. Later flowers such as foxgloves (*Digitalis*) should be planted at or near the edge, where they will still get sunlight once the leaves have appeared on the trees. Climbers such as honeysuckle (*Lonicera*) or clematis are also best situated at the woodland edge where you can appreciate the plants as they bloom. It is advisable to always obtain your seed or plants from a reputable source that does the propagation themselves. Never buy bulbs or plants that have been collected from the wild. Your aim is to create a habitat, but not by destroying another.

## ASSOCIATED PLANTING

Perhaps the easiest way to mimic a woodland habitat in a smaller garden is to link a few trees with shrubs and understorey trees in order to provide the shelter and food plants that wildlife needs. These shrubs – particularly if they are deciduous – can provide a larger space in which to plant "woodland herb layer" species. Doing this will also widen the edge of the habitat and provide extra coverings around the base of trees. There is, of course, no problem in having a few decorative species in or around your woodland. Try a few rhododendrons, mahonias, lilacs and hydrangeas to provide additional colour and interest if you have enough space. They will all provide shelter and look attractive when they are in flower.

## EDGE ENHANCEMENT

Woodland edges are often the most valuable area in many types of woodland for a variety of wildlife and plants. The trick with any wildlife-friendly area is to make sure that these boundaries are as long as possible. Fashioning them into "scalloped" or bay shapes will usually achieve this and each scallop or bay may contain different plants or shrub species. The clearings inside your woodland (if it is large enough) are also important. When you create these clearings, ensure that they are sufficiently long to allow plenty of sunshine into each one. Woodland glades should not be less than 7m (23ft) across and are best if they are irregular in shape.

Remember that the direction of the sun in your garden will affect the type of plants that you can grow at the woodland edge, and butterflies, for example, will prefer a sunny aspect. If the bays or clearings in your woodland area are mainly intended for long grass, then this may only need cutting every two to five years unless, of course, you wish to have a secluded seating area that may need more frequent mowing to maintain access.

*Above: Hellebores and* Anemone blanda *make an ideal under-planting for trees, providing colour in early spring.*

Left: *Hornbeam (*Carpinus*), grown as a decorative hedge, can be underplanted with a selection of woodland flowers for added interest in the spring.*

# WILD FLOWER LAWNS

*Compared with a closely mown pristine lawn, an area of rough grass with flowers growing in it can provide a rich haven for a diverse range of wildlife. In nature, many attractive and species-rich habitats develop over time but in the garden, things may need a helping hand. You do not have to let the whole of the turfed area go untouched. Simply leave an area of grass uncut for some of the year and plant it up with your own choice of wild flowers to create a rich habitat.*

Above: *Lawns and areas of long grass can easily be transformed into a stunning display of summer flowers.*

## PLANTING AND MAINTAINING A WILD FLOWER MEADOW

Small areas of flowery grassland seem to work best when co-ordinated with hedges, shrubs or trees. They are not necessarily spectacular from a distance and need close inspection to appreciate the detailed tapestry of colour and form. Think carefully about where you would like to site such a feature. Always choose a simple mix of species that are well adapted to the conditions in your garden. Take a walk around your home area to see which local or well-adapted species thrive in similar soil types and aspects to your own.

## ANNUAL FLOWERS OR PERENNIALS?

Many annuals have attractive flowers and seem ideal for flower-rich lawns but most require yearly soil disturbance and open ground. Poppies and cornflowers are good examples of showy annual plants that benefit from such conditions. Annuals are usually better treated as a separate display. Try planting some wheat or other grain along with the annuals and leave this for foraging birds and mammals. Don't try and harvest the wheat, just cut it down in late autumn and rotavate the plot ready for the spring.

Wild flower meadow species are perennials, which are adapted to life in permanent grassland. The easiest way to make a wild flower lawn is to plant small wild flower plants, directly into an existing lawn. Many wild flowers are easily raised from seed that is available from specialist suppliers. Sowing and growing this is generally the same as for any other herbaceous plant but you should use potting mix that is low in nutrients for the best results. A late autumn or early spring sowing will provide plants that are large enough to plant out in early to mid-summer.

## HOW TO SOW WILD FLOWERS

**1** *The most satisfactory way to create a wild flower meadow is to sow a special mixture of wild flower seeds. Remember to completely clear the ground of all perennial weeds before you start.*

**2** *To bury the seeds, simply rake in one direction and then in the other. It does not matter if some seeds remain on the surface. Keep the area well watered until the seeds germinate. Protect from birds if necessary.*

## ADDING INTEREST TO NATIVE GRASSLAND

**1** *For a very small area, wild flower plants may be more convenient. You can raise your own from seed or buy them. Plant into bare ground or in an existing lawn.*

**2** *Keep the plants well watered until they are established. Several years of successional planting may be needed to fully establish your wild flower lawn.*

Plant these out about 10–20cm (4–8in) apart in groups of 9–15 to ensure that the group can compete with the grass. Mark where you plant them so that you can see which ones have succeeded later.

If your plants do not establish the first time around, then it is worth trying again. Two failures should tell you that they are not suited for your conditions. You can always try a few non-native plants that have proven wildlife value. Prairie plants such as *Echinacea* are very useful in long grass. Try to avoid rare species, as they are likely to be particular in their habitat requirements, and always consider the attractiveness of plants to insects, birds or other wildlife when deciding what to grow.

## NATURALIZING BULBS IN GRASS

Bulbs are potentially one of the easiest plants for flowery lawns. Many early-flowering species are suitable, including crocus, iris and snowdrops. Others, such as *Narcissus*, *Puschkinia*, fritillaries and *Leucojum*, provide good displays later in the spring. Planting bulbs is quite simple. Planting holes can be dug singly with a trowel or spade to the required depth – usually two to three times the height of the bulb. Bulbs should be placed with the base plate firmly in the bottom of the hole. An alternative method for large groupings of small bulbs like crocus and snowdrops is to cut an "H" shape in the grass surface and peel the grass back in two "flaps". Place the bulbs underneath with the top uppermost and gently replace the flaps, firming them carefully. Any group of bulbs should be denser at the centre, gradually becoming wider spaced toward the outside, as this will give a natural appearance. Bulbs such as *Narcissus* may survive for many years but some smaller types – crocus being a prime example – may be eaten by rodents.

Above: *Daffodils (*Narcissus*) are an ideal bulb to naturalize in lawns, giving spectacular early-spring interest in the wildlife or ornamental garden.*

## HOW TO NATURALIZE BULBS IN A LAWN

**1** *Lift an area of turf to create an H-shaped cut. Slice beneath the grass until you can fold back the turf for planting. Loosen the ground, as it will be very compacted. If you want to apply a slow-acting fertilizer, such as bonemeal, work it into the soil at the same time. Scatter the bulbs and plant them where they fall for a natural effect.*

**2** *Use a trowel or a bulb planter for large bulbs, making sure that the bulb will be covered with twice its own depth of soil when the grass is returned. Firm down the soil and then return the grass. Firm once again if necessary to make sure that the grass is flat, and water well. Water the grass again in dry weather.*

**3** *Special bulb planters can be used for large bulbs. The planters remove a cylindrical core of soil.*

**4** *Place the bulb at the bottom of the hole on a bed of gravel to improve drainage, if necessary, and replace the plug of earth.*

## CARE AND MAINTENANCE

The time of year that you mow your meadow will influence the species you can grow and also when it will look good. If bulbs are not being grown in the grass then a spring cut can help keep a summer wild flower area tidy, especially after a mild winter. A high cut is best, especially if wild flowers have started to produce leafy growth. Cutting in mid-spring will produce a flowering peak in mid-summer. A slightly later cut in late spring will delay the peak of flowering by a few weeks.

Once flowering has finished, the long grass should be cut down. Spring-flowering meadows are best not cut until after flowering. If bulbs are included then the area should not be cut for six weeks after they have flowered. A second cut in mid-autumn will tidy the area ready for the winter. Summer meadows are usually cut from late summer to mid-autumn. All cuts must stress the grasses but minimize damage to wild flowers. Cuts should be between 30–70mm (1¼–2¾in) in order to achieve this.

Cuttings should be removed to help reduce fertility (as this will help your wild flowers) and to prevent long cuttings smothering the plants below. The cuttings should be left on the ground for three to five days, though, to allow insects to move back into the cut grass below. A portion of lawn may be left completely uncut to protect over-wintering insects, but the portion left must be rotated each year to make sure that the wild flowers survive.

# WILDLIFE PONDS

*Water is a key element in a wildlife garden. Garden ponds attract an enormous range of living creatures, such as dragonflies, newts and birds, to name just a few of the insects and animals that will visit the garden. Some will come to drink or bathe, others will set up permanent residence there, adding to the beauty and diversity of your garden. A pond not only provides an attractive feature in your garden, but also has far-reaching benefits to wildlife.*

Above: *Pond plants are essential to the health and balance of the habitat as well as being highly attractive.*

## CREATING A HEALTHY ENVIRONMENT FOR A POND

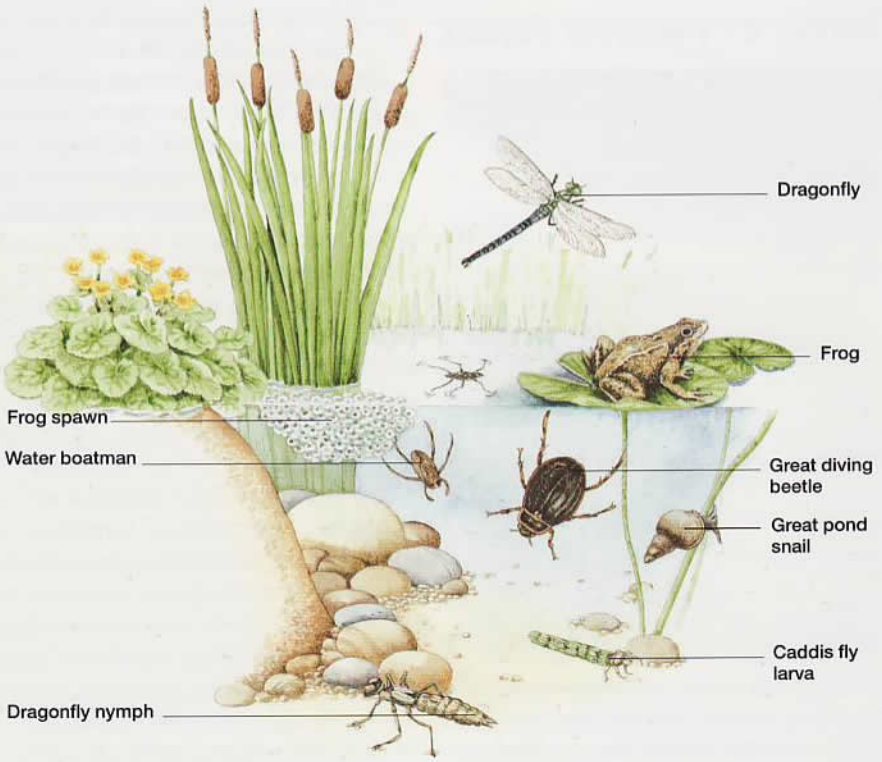
There are a number of points that you must be aware of if you want to provide a safe and healthy environment for wildlife. A pond is always best sited in a sunny position. This is because many pond plants will not prosper in shade, while the water may also be rather cold until the early summer. Shade within the pool is best achieved by surface vegetation, although a pond may have up to a third of the surface in shade if the remainder is well lit. You should also avoid a site near to overhanging trees whose shade can cause the water to be colder for longer in the spring. Falling leaves can cause a build-up of nutrients and increase the potential for toxic tannins in the water. The roots of some species may also interfere with the lining of the pond and can, in extreme cases, cause serious damage.

## WATER FOR THE POND

Never fill your pond with tapwater, which often contains many additives, most notably chlorine. Much tapwater can have a high pH and may contain phosphates or nitrates. These can raise the pond's nutrient levels and promote algal growth. Water runoff from nearby lawns or borders can have much the same effect. If the water level becomes very low during the summer it is possible to use solarized mains water to top up your pond. This involves filling large containers with tap water, partially covering the tops and leaving them to stand in the sun for a couple of days. It removes chemicals like chlorine and, although not as good as rainwater, it will stop your pond from drying out. The majority of pool life requires a still environment, so avoid introducing pumps, fountains or filters.

## A CROSS-SECTION OF A WILDLIFE POND

*Displayed below are some of the more common inhabitants of the garden pool which go towards forming a healthy and balanced ecosystem.*



## POND SIZE

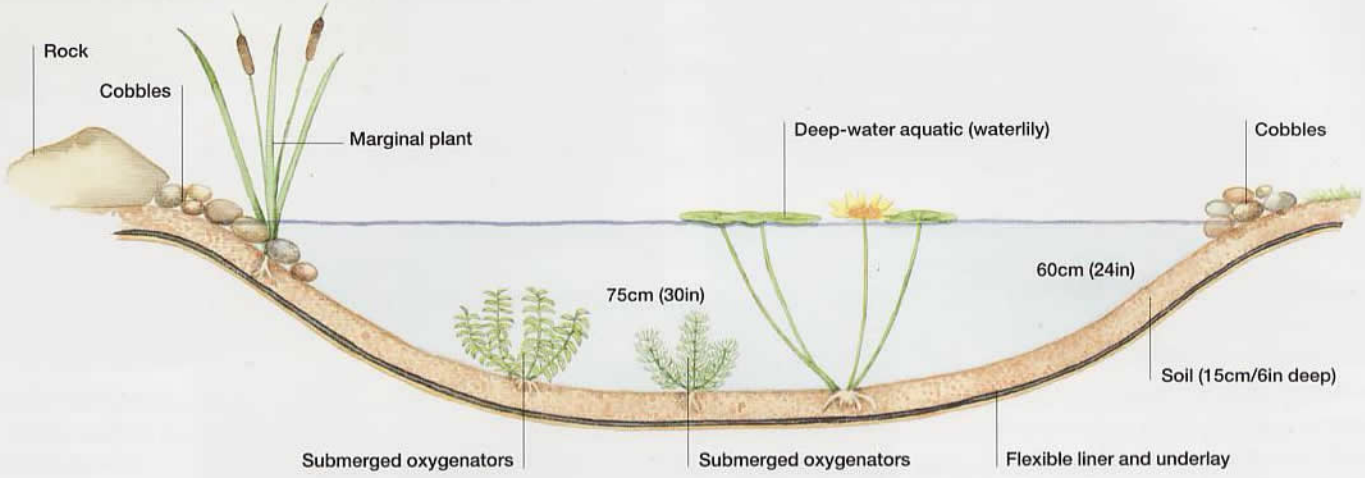
Even small-scale ponds can support an amazing diversity of life. The shallows are the most important areas for wildlife but a depth of at least 60cm (24in) must be reached in some parts to give creatures a place to which they can escape in extreme heat, cold or drought. The greater the surface area of a pool, the deeper it has to be (at its deepest point) to maintain an even temperature throughout the year. The average pool will need to be about 1m (3ft) deep.

## STOCKING A POND

Ponds that are designed to attract wildlife should be colonized naturally within a couple of years. This is the best method for stocking your new pond in the first instance as it is providing a breeding place or hibernating area for those creatures already established in your area. Introducing frog (or other amphibian) spawn can sometimes spread diseases such as red leg that can devastate populations of frogs and other amphibians. Never attempt to introduce adult amphibians to your pond. They have an amazingly strong homing instinct and can die in the process of finding their way back.

## A WILDLIFE POND

*Wildlife ponds depend upon correct planning. Ponds must be both deep enough and possess the right balance of plant types. These plants will provide habitats, shelter, and maintain a balanced environment for the wildlife in the pond.*



Avoid introducing fish to small wildlife ponds, as they can exclude other wildlife. Sticklebacks can wipe out the tadpoles of frogs and newts. Fish also eat valuable water-living crustaceans that help to control the growth of water algae and their droppings promote algal bloom.

### PLANTING

Bank-side vegetation provides cover for animals entering or leaving the pond. Choose a selection of marginal plants, submerged plants and plants with floating leaves. Leaving long grass around a pond will also provide important cover for wildlife. Gently sloping sides make it easier for creatures to climb in and out of the pond.

Pond dwellers, such as dragonflies and caddis flies, need vegetation to climb out of the water so that the adult may emerge. Small reeds such as the lesser bulrush are ideal but any plants that grow about 40cm (16in) or more above the normal water surface will do.

A log pile nearby will provide a place for hibernating frogs and toads, as well as being a habitat for many other creatures. Add an escape log to help small mammals get out of the pond if they fall in.

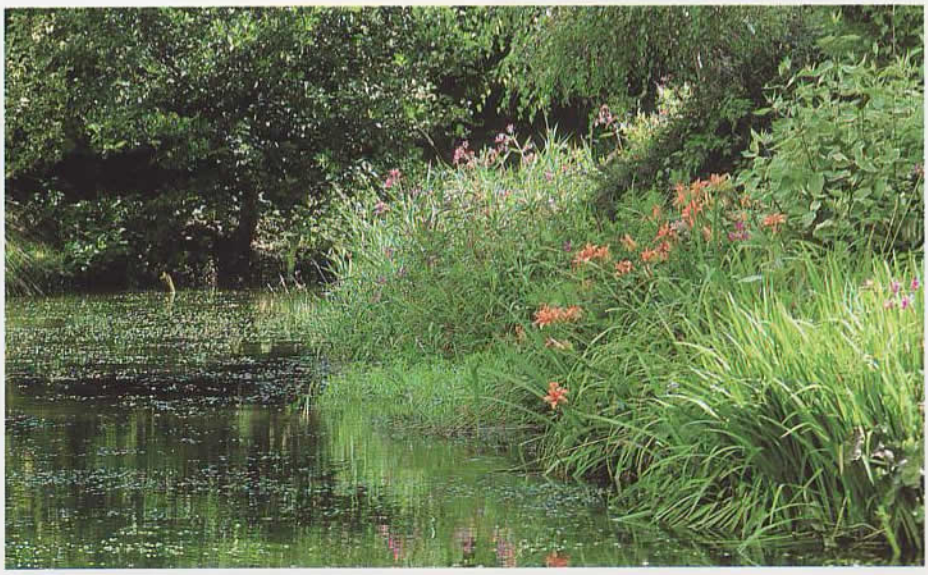
Ideally the water surface should have a third or more covered with plant leaves such as water lilies, water soldier, frog-bit or even duckweed. These help keep the water cool, provide shelter and breeding cover for wildlife and help to prevent the development of algae in the water.

Plants that are to form part of your pond habitat should always be grown in a nutrient-poor potting mix. Slow-release fertilizers effectively act as an algal "time bomb", steadily releasing a supply of nutrients that encourage green water and blanket weed development.

Oxygen is essential for the growth and development of pond-dwelling creatures and can easily be boosted by the inclusion of plants that release it directly into the water. These are plants that are entirely aquatic and do not emerge above the water surface. Plants such as milfoil and Canadian pondweed are often used for this purpose.

Native plants should be a first choice for a pond. Many are showy and often rare or endangered in the wild. If you decide to use natives, never take them from the wild. Always buy them from a reputable nursery or take small offsets from a friend's pond.

Some plants are just too vigorous to be included and will rapidly outgrow their situation. Reedmace (*Typha latifolia*), reeds such as phragmites, floaters such as duckweed (*Lemna*) and the *Azolla* fern are all potentially problematic and should only be included where space permits. They are the equivalent of aquatic weeds and may cause maintenance problems.



Right: *Even a small garden will benefit from a tranquil wildlife pond where animals can come to drink.*

# PROVIDING SHELTER

*As well as needing water and food, wildlife occupants and passing visitors to the garden need a secure place in which to shelter, where they can feed, nest, breed or escape from predators. Almost every part of the garden can potentially shelter wildlife and the key is not only to provide the right kind of cover but also to make sure that it is not disturbed once it is occupied. These sites can take the form of natural plantings or man-made shelters.*

Above: *Providing winter cover such as this lacewing hotel for beneficial insects ensures a healthy population for next season.*

## TYPES OF SHELTER

In nature, evergreen trees and shrubs provide year-round cover from weather and predators, while deciduous ones give summer cover for nesting and protection. Dead trees provide habitats for owls, woodpeckers and bats, while fallen logs are host to a wide array of ground dwellers such as wood-boring beetles and other insects.

Centipedes and ground and rove beetles that are active all year round need undisturbed soil, stones and logs. Frogs, toads and newts hibernate through the coldest months, often overwintering in damp hidden sites. Place stones and logs near to a pond and ensure that it has shallow edges and sloping sides. Newts prefer overhanging vegetation to shield them on entering and leaving.

Think about where specific creatures live in nature and aim to mimic these habitats. Sometimes this will involve using the natural landscape or erecting a purpose-built shelter.

Left: *Logs and branches, left over from pruning or tree felling, can be left as a habitat or winter shelter for wildlife.*

## LOG PILES

These are an essential part of any wildlife garden because they offer shelter and food for a wide range of different organisms and insects that will in turn provide food for other visiting animals.

Log piles make an excellent place for frogs, toads, lizards, hedgehogs and other wildlife species to shelter, find food, and raise their young. Build a permanent log pile in a shaded area, and let it decay naturally. The logs form food for fungi and insects, while providing shelter for reptiles and small mammals. Dead wood on the ground and especially up in the trees is a very important source of nourishment for insect-feeding birds, such as woodpeckers and tree creepers.

Left: *A shady part of the garden, under the cover of trees, is the ideal place for a log pile. Log piles are both useful for hibernating animals and as a food source for beetles.*

## TIDINESS

You should not be in too much of a hurry to clear and tidy up your garden in the autumn, as this will provide shelter during the winter months for a wide variety of garden wildlife. Always be selective, preferably removing only piles of diseased debris. The later you can leave your winter clearance, say until early spring, then the greater the numbers of animals there will be successfully overwintering.

## WHICH SPECIES SHOULD YOU SHELTER?

There is a wide range of species that can benefit from cover in your garden. However, you should always try to assess the likelihood that these creatures will actually visit your garden in the first place. There is little point in putting up luxury accommodation for creatures that will never even see it, much less shelter within. The following are some of the creatures that may benefit from a shelter in your garden.

Above: *It is advisable to position shelters for beneficial insects near to a suitable habitat or to a source of food so that they can find them easily.*

Above: *Pollinating insects such as bees need both shelter and protection. Bees are very important inhabitants of a wildlife garden; honeybees pollinate plants in the garden.*

**Bats** These are probably the most elusive of our garden visitors and because of their nocturnal lives we know very little about them and often, rather unfairly, fear them. Bats roost during the day in tree hollows, in dense shrubs or climbers, and in buildings, although during winter they hibernate, often in deeper, solid places with an even, cool temperature. These fascinating mammals are declining in number due mainly to the loss of roosts and feeding areas, and the increasing use of pesticides. One of the easiest ways to help bats is by putting up bat boxes. These should be located in a sheltered position that gets morning sun and afternoon shade.

**Birds** The lively activity around your bird table or feeders shows that it can be easy to attract more birds into your garden. Birds need more than just a source of food, though, and suitable nesting sites can be essential for some common garden species. Trees, shrubs and climber-covered walls and fences will provide shelter and nest sites.

Though the term nesting box implies birds may nest in them, only a few species use natural or man-made cavities. Most look for shelter in vegetation, with shrubs being perhaps more valuable than trees for this purpose. You should note that regular close pruning of shrubs might cause growth that is too dense for birds to navigate easily. Try to use native species where possible. Hedges that also produce berries are a good source of food for birds in the colder months.

**Butterflies** These also require shelter from the elements and a place to roost. The foliage of shrubs is useful as an overnight roost, as are patches of tall grass. You can also provide a place for butterflies to roost, perch, or even hibernate by building a log pile and stacking the logs crosswise to create as many open spaces as possible. The ideal log pile size is about 1.5m (5ft) tall and 2m (6½ft) long. You can also buy a butterfly hibernation house, although there is little evidence that these are ever actually used by butterflies.

**Hedgehogs** If you lean a sheet of wood at an angle against a wall and stuff it with dry leaves, this will provide a suitable nest for hedgehogs. They will also nest under raised sheds and beneath hedgerows, as long as there are plenty of dry leaves for bedding. You can also provide a winter box in an old compost heap or leaf pile for hibernation.

Above: *You can encourage butterflies into your garden by planting wildlife-friendly plants such as these purple verbenas.*

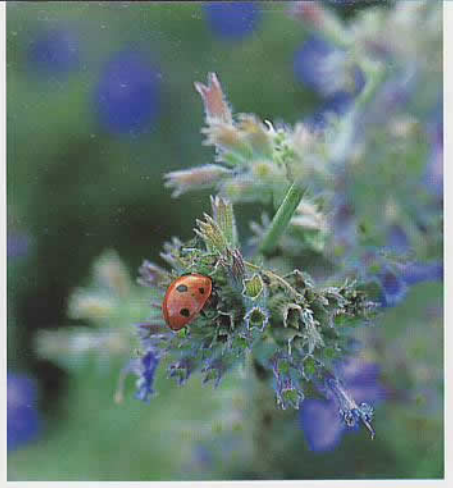
**Reptiles and amphibians** Rocks, logs, and leaf piles offer cover for small mammals, reptiles, amphibians and insects. In the autumn, try constructing small rock piles that can provide lizards, reptiles and amphibians with a warm winter retreat. If you have a pond, leave brushwood and leaves or rock piles near the bank to provide shelter for amphibians as many of these hibernate in damp areas on the land.

**Pollinators** Bumble-bees can overwinter in a small terracotta pot filled with moss or finely shredded newspaper. Bury the filled pot upside down and protect the hole from rain with stones, but leave a tiny gap for the bee to get in and out. Masonry bees can be encouraged to take up residence by tying a bundle of bamboo canes together – lengths of about 25cm (10in) are ideal – and then placing them inside a length of old plastic pipe that is about 5–7.5cm (2–3in) longer than the canes. They will make nests inside the hollow bamboo canes and lay eggs within these that will hatch out the following spring. Always place the pipe in a sunny sheltered position where rain will not reach it. You can also buy purpose-built masonry bee shelters.

**Predators** Lacewings will shelter in a similar construction to that used for masonry bees. Ready-made lacewing hotels are available and are impregnated with a pheromone that attracts the adults in the autumn. Ladybird (ladybug) shelters are also marketed commercially for the same purpose. You can also buy the pheromone with which to impregnate your own home-made shelters.

# PLANTS TO ATTRACT WILDLIFE

*Plants are the single most important factor when it comes to attracting wildlife into your garden. They provide a food source and shelter for visiting bees, butterflies, moths and a whole host of beneficial insects. Even if your garden is tiny, you can still introduce a selection of useful plants by planting tubs of brightly coloured and nectar-rich summer flowers and pots of sweet-smelling herbs such as lavender and rosemary.*



Above: *Beneficial predators such as ladybirds (ladybugs) will be attracted to the garden if you include the right species of plant.*

## PLANTS FOR FOOD AND SHELTER

Planting colourful, nectar-rich plants attracts butterflies and other beneficial insects. Choose plants that will provide the visitors with nectar from early spring to late autumn. This of course has the added benefit that your flower beds will be brimming with colour for most of the year. Combine selected species of herbs, wild flowers and cottage garden plants in a herbaceous border to create a butterfly or bee border.

To encourage breeding insects, allow a few nettles and grasses to grow in a secluded corner of the garden or let ivy trail up your fence. These will provide sites for female butterflies to lay eggs and a food source for caterpillars.

Wild or single-flowering varieties of plants are often best for wildlife. You should not be too eager to dead-head plants in autumn.

Many birds feed on spent flower heads such as those of forget-me-nots and pansies. Leave perennial flower stems in autumn, as birds will be attracted to them, searching for seeds and hiding insects. Nesting birds need insects to raise young, so try early-flowering plants such as aubrietia that attract aphids and provide a source of food.

Left: *Plants with composite flower-heads, such as thistles and daisies, readily attract insects to the garden.*

A hedge that is left relatively undisturbed by the gardener can prove a rich habitat for a diverse range of wildlife. Dense hedges give birds protection from predators and provide windbreaks. The thick undergrowth encourages many species of small bird to take shelter and unclipped hedges of all types have more chance of bearing flowers and fruit.

If your garden is large enough to have at least one large tree then this will provide perches and nesting sites for many birds. Native trees are valuable to insects, birds and other animals as they provide better shelter and food than introduced species. The best trees are those that produce

Above: *Choose plants such as roses that have berries or edible fruits for birds and mammals to feed on.*

Above: *Sunflowers (*Helianthus annuus*) provide food for insect pollinators as well as late seeds for overwintering birds.*

Above: *Scabious (*Astrantia*) can be used in flower borders or in wild flower lawns in order to attract insects such as bees.*

seeds or fruit, as these are often a valuable source of food for many birds in autumn or winter.

Shrubs provide shelter for birds, enabling them to nest safely. Choose shrubs such as *Pyracantha*, *Cotoneaster* and *Viburnum* that produce a good crop of berries for the birds to feed on. Climbers are attractive to birds, especially if they are late flowering or bear fruit and seeds for winter food.

Annual species, planted on vacant patches where quick reliable displays of colour are required, will produce an outstanding array of colour, and their nectar and seeds provide valuable food for many types of insect.

Meadow-plant species will provide colour while the foliage of naturalized bulbs withers down. A fine early display can be created under deciduous trees before the soil becomes too dry and shaded, and grassy banks provide a marvellous opportunity for creating a mini meadow. An informal lawn is the intermediate step between a formal lawn and a meadow and is often created adjacent to a formal lawn and sown at the same time. It contains species tolerant of close cutting and if mowing is relaxed in summer, an enchanting display of flowers can be enjoyed for many weeks. When mowing is recommenced no harm will come to the plants, and the practice can be repeated annually.

Above: *Encouraging beneficial insects into your garden by including insect-friendly plants can help to create a natural balance.*

Shaded areas of the garden often present a problem for gardeners, but there are many varieties of woodland plants – often including some of the most beautiful wild flowers such as anemones and foxgloves (*Digitalis*) – that will thrive in these conditions. A woodland area planted with native trees and shrubs is the ideal backdrop for bulbs and woodland wild flowers. This habitat provides a continual source of interest throughout the year and attracts insects, birds and mammals.

Plants growing along and in hedgerows are particularly useful to attract wildlife, especially if the hedge is made up of native species. Plants for sun, shade or semi-shade should be selected depending on the aspect of the hedgerow. New hedgerows should be allowed to establish free of competition for two to three years before associated plants are introduced. Hedges provide corridors for wildlife and sources of interest throughout the year, with attractive foliage in spring, flowers in summer and berries, hips or leaf colour in autumn and winter.

Plants that grow in or around ponds act as a magnet to surrounding wildlife. Damp soil borders and marshy areas are the ideal habitat for many species of wild flower.

Dry-stone walls can also be exploited by planting up nooks and crannies with wild flowers adapted to the conditions, adding interesting foliage and colour.

Combinations of wild flowers can also make excellent subjects for patio tubs, pots and hanging baskets, as many of them are tolerant of drought and have a spreading habit, making them ideal for low-maintenance containers.

Left: *As its common name of butterfly bush suggests, buddleia is a particularly excellent source of nectar for butterflies.*

## TOP 20 GARDEN PLANTS TO ATTRACT WILDLIFE

There are literally thousands of plants that all have the potential to attract various forms of wildlife to the garden. Some plants, however, are more effective at this than others. Twenty of the best plants for attracting wildlife that are easy to grow are listed below.

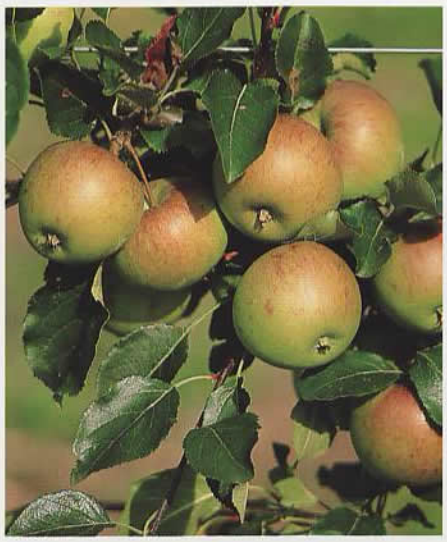
| PLANT | | WILDLIFE ATTRACTED | BENEFITS TO THE GARDEN |
|---|---|---|---|
| ***Achillea millefolium*** **(Yarrow)** A vigorous herbaceous perennial that grows to a height of 60cm (2ft). Flower colour ranges from white through to reds and oranges. | | An abundance of hoverflies can be found nectaring on the flowers in summer. Also attracts bees and bumble-bees. | Hoverfly larvae are an excellent addition to the garden, providing efficient control of aphids. The larvae can eat vast amounts of aphids during this part of the life-cycle. |
| ***Angelica archangelica*** **(Angelica)** A tall, upright, herbaceous perennial, more often grown as a biennial, which grows to 1.8m (6ft). The architectural flower-heads bloom in early to mid-summer. | | Bees, butterflies, hoverflies, insects and birds all congregate around the huge flower heads of this garden bloom. | This plant can be likened to a supermarket where many species gather to stock up on food. Count the number of species on one bloom, it is amazing. |
| ***Aster novi-belgii*** **(Michaelmas daisy)** The flowers of this herbaceous perennial provide a rich source of late nectar. A full range of sizes and colours are available. | | In late summer and autumn butterflies and bees visit the flowers. Birds eat the seed after ripening. | This plant provides a valuable late source of nectar. Butterflies will use this food to strengthen them up for winter hibernation or to produce eggs to overwinter. |
| ***Aurinia saxatilis*** **(Golden alyssum)** Also known as *Alyssum saxatile*, this herbaceous perennial forms a carpet of yellow flowers in spring. | | Butterflies, bees and early flying hoverflies are attracted to the bright yellow flowers of this popular rock garden plant. | A very useful source of nectar for all early insects, especially early season or overwintering butterflies. |
| ***Buddleja davidii*** **(Butterfly bush)** This deciduous shrub is often quoted as the saviour of the British butterfly population due to the high quantities of nectar it produces. | | As the name suggests, this is an excellent plant for attracting butterflies. Also useful for a variety of nectar feeders, including bees and moths. | Like asters, this is an excellent feeding stop for migratory and resident butterflies. The caterpillars are a good source of protein for birds. |
| ***Centranthus ruber*** **(Red valerian)** A herbaceous perennial that grows to 60cm (2ft). It performs well in poor dry soils and does especially well in seaside locations. | | One of the best flowers for butterflies, providing nectar for small tortoiseshells, peacocks, red admirals and white and yellow butterflies. | Butterflies are a good indicator of the health of the environment. Their caterpillars are a good source of protein for nesting songbirds. |
| ***Cerinthe major*** **'Purpurascens'** A small herbaceous perennial that flowers in spring. Produces fantastic blue flowers with lilac bracts. It self-seeds freely. | | Bees love the blue flowers and congregate in vast numbers while the plant is in flower. | This early flowering perennial gives a boost of nectar to resident bee populations, which are good pollinators. |
| ***Eryngium giganteum*** **(Miss Willmott's ghost)** A short-lived herbaceous perennial that reaches a height of 90cm (3ft) and has beautiful steel-blue flowers. | | This plant hums with bees and bumble-bees during its long summer-flowering period. | An outstandingly beautiful plant that attracts bees which will pollinate your plants. Good for naturalizing in wild areas. |
| ***Eschscholzia californica*** **(Californian poppy)** An annual that produces striking orange, cream, red or yellow flowers which will bloom all summer. This is a small plant, reaching 45cm (18in) in height. | | Hoverflies, bees and bumble-bees are attracted to this plant. Once it is sown, it will self-seed freely round the garden. | The bright orange flowers attract hoverflies, the larvae of which are extremely voracious predators of aphids. |
| ***Eupatorium cannabinum*** A tall plant that produces large heads of fluffy pink flowers in late summer. This herbaceous perennial is a must for the wildlife garden. | | Attracts butterflies and bees. As well as looking fantastic, this plant is one of the best for providing nectar to adult butterflies. | From mid-summer onwards, this decorative plant offers a rich and steady source of nectar and is a firm favourite with visiting butterflies. |

| PLANT | | WILDLIFE ATTRACTED | BENEFITS TO THE GARDEN |
|---|---|---|---|
| ***Helianthus annuus*** **(Sunflower)** If you want to make a statement, grow a few of these in your garden. They have enormous yellow, red or orange heads with some tall varieties easily reaching 2m (6½ft). | | Birds such as greenfinches and bullfinches will eat the seeds. Also visited by honeybees and bumble-bees when in flower. | The seeds provide a late-summer boost to the diet of birds and some small mammal species. Good for encouraging birds into your garden. |
| ***Humulus lupulus*** **'Aureus' (Golden hop)** A vigorous climber with twining stems. It is unusual in that it dies down every year. The female plants produce hops that are used in flavouring beer. | | Caterpillars of the beautiful comma butterfly and button snout moth feed on the golden foliage. | Food plants for caterpillars and larvae are an invaluable part of a wildlife garden, otherwise we would not be graced with the adult butterflies. |
| ***Lavandula angustifolia*** **(Lavender)** A compact bushy shrub that sports many varieties to choose from. It produces fragrant pink to purple flowers in early summer. | | The fragrant blooms attract many different species of bees, bumble-bees and also white and blue butterflies. | Insect-eating birds are attracted to feast on the insects drawn to nectar on these fragrant bushes. |
| ***Lonicera periclymenum*** **(Honeysuckle)** A climber with twining stems reaching up to 6m (18ft). It bears sweetly scented, pink and cream flowers in early summer, with red berries appearing later. | | Nectar provides food for bumble-bees, bee hawk moths as well as elephant, lime and privet hawk moths. Fruit-eating birds will feast on the berries. | A superb plant for night-flying moths that should be placed next to the house so you can enjoy both the fragrance and watch these night-flying beauties. The moths are also a good source of protein for birds and bats. |
| ***Nymphaea alba*** **(Waterlily)** An aquatic plant that has large round floating leaves with beautiful white flowers in the summer months. | | Adult frogs and dragonflies use the floating leaves of this aquatic plant for basking on. The leaves also provide cover for tadpoles of newts and frogs. | Adult frogs eat slugs and snails. The tadpoles help to control algae in the pond, as it is part of their diet. |
| ***Phlox paniculata*** The lovely, sweetly scented flower heads provide a colourful display in late summer. This 90cm (3ft) herbaceous perennial prefers a moist soil in light shade. | | This plant will attract adult butterflies and moths, which will appreciate the nectar from the flower heads in late summer to early autumn. | The moths nectaring on this plant will provide a tasty meal for wandering bats. Butterflies flying during the day will provide a meal for hungry birds. |
| ***Rosmarinus officinalis*** **(Rosemary)** A dense bushy shrub with aromatic foliage growing up to 1.5m (5ft) tall. It bears purple to blue flowers in mid-spring to early summer. | | Almost unrivalled in its ability to attract honeybees, butterflies and hoverflies to its nectar-rich flowers. | Honeybees pollinate many garden plants and trees. They are welcomed by farmers into fruit orchards. |
| ***Sedum spectabile*** **(Ice plant)** This small herbaceous plant is one of the best butterfly plants. It has thick succulent leaves and stems that are well suited to growing in hot well-drained positions. | | An old favourite for the herbaceous border, Sedum is extremely useful to butterflies, bees and hoverflies as a late summer source of nectar. | Provides a good source of nectar late in the season that is a positive benefit for overwintering butterfly species to build up their energy. |
| ***Sorbus aucuparia*** **(Mountain ash)** A wonderful tree for the small garden. It has attractive white flowers in the spring and bears red fruit in the autumn. It can reach heights of 12m (36ft). | | The flowers are excellent for feeding bees and other insects in the spring whereas the berries are consumed by many species of birds. | The tree can attract up to 30 different species of insect, not including the birds and small mammals it feeds, providing a meal for many. |
| ***Verbena bonariensis*** **(Tall verbena)** This versatile plant can be grown as an annual or short-lived perennial, reaching up to 1.8m (6ft). The purple-flowering spikes bloom in late summer until the first frosts. | | This is a fantastic plant for nectaring butterflies such as the small tortoiseshell, peacock, red admiral and comma. It is perhaps more effective than the more well-known buddleia. | Good for planting in large groups throughout the garden to attract large numbers of butterflies and bees to pollinate plants and to provide food for garden birds. |

# THE KITCHEN GARDEN

The kitchen garden is a paradise for gardener and cook alike. Few pleasures in life can compare with the satisfaction of harvesting and eating fresh produce from your own garden. There are many design possibilities when planning a kitchen garden. Some gardeners prefer to lay out their vegetable plot in neat rows; others choose an edible landscape that is ornamental as well as functional. There is also a seemingly endless choice of varieties in seed and nursery catalogues which can be confusing, but merely reflects the popularity of home-growing.

Left: *Kitchen gardens can provide a summer spectacle as well as a wealth of fresh, home-grown food for your table.*



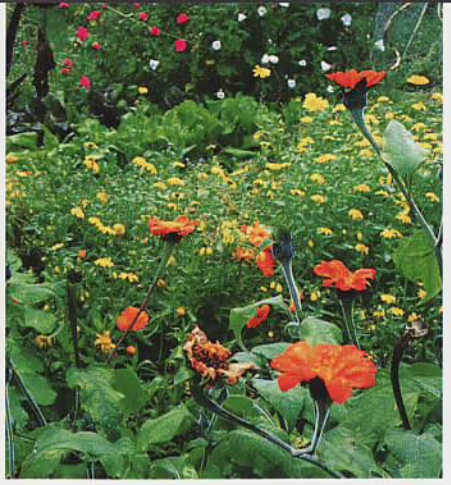
Above: *Fruit such as pears and apples is one of the most welcome delights of autumn in the kitchen garden.*

Above: *Companion planting helps to keep plants healthy and also looks attractive throughout the summer.*

Above: *Kitchen-garden plants can be just as decorative as those grown for their ornamental qualities.*

# PLANNING A KITCHEN GARDEN

*Growing your own vegetables, herbs and fruit ensures that the food you eat is fresh, tasty and chemical-free. The healthiest food is found closest to its source, so freshly picked produce from your garden is both tastier and better for you than that which has travelled long distances by air, sea or road. Your garden will also be more appealing when it is planted with a wide selection of plants that will attract an equally diverse range of wildlife.*



Above: *A well-planned kitchen garden, with companion planting, can be a feast for the eyes as well as the table.*

## WHAT DO YOU WANT FROM YOUR KITCHEN GARDEN?

An ideal starting point is to make a list of all the vegetables and fruit that you eat on a regular basis, adding in a few that you are curious about and would like to try. The next stage is to look at the size of your garden and consider if there is enough room to grow everything that is on your list. Think about the quantity needed to feed your family. There is no point in planting ten apple trees for a family of four. It is a good idea to start with a few easy crops to build your confidence and progress from there.

Left: *Peas and beans can easily be trained up supports, giving height and structure to the kitchen garden.*

Many edible plants, especially vegetables and herbs, are easy to grow and can be ready for harvesting in a short space of time. Children love to sow and grow less difficult crops, such as spring onions (scallions), radishes, carrots and lettuce. Growing fruit is usually a longer-term investment, as many types, such as apples, pears and blackcurrants, for example, will take several years to crop. Once they start to produce fruit, however, your investment will pay off, as they will continue to crop for many years to come and are less time-consuming than vegetables.

Furthermore, you do not need acres of space to enjoy growing your own fresh fruit and vegetables. In fact, even a small garden will support an edible crop or two. You could grow potatoes in barrels, herbs in pots and fruit trees in ornamental containers. If you live in an apartment, you can use window boxes and containers to grow fresh herbs and vegetables. Try planting hanging baskets with trailing tomatoes, herbs or fruits such as strawberries to overcome space difficulties. Edible gardening involves using any space that is conveniently available. It also promises a colourful garden and unusual ways to feed your family.

## DESIGNING THE GARDEN

There are a number of points that you will need to consider in order to get the most out of your kitchen garden and to ensure that the food you produce is safe and fresh. Siting your crops next to a busy road, for instance, can mean eating produce that is polluted by cars. When siting the crops, think carefully about your own garden environment. Each garden is different and has specific requirements for growing various crops. Check the pH of your soil before getting underway as vegetables such as cauliflowers and cabbages will not grow well if the soil is too acidic (under pH of 6.5). As well as testing the pH level, test the soil for nutrients. The results will indicate if there is any need to improve the soil before planting.

The aspect of your garden is also critical in the siting of your plants. Fruit, for example, needs plenty of sun exposure in order to ripen properly and develop flavour. Fruit trees are also often best sited over a lawn to facilitate fruit collection.

Any design needs to consider the difference between annual and perennial crops. Annual vegetable crops, such as potatoes, carrots, cabbages and beetroot, need to be rotated within the vegetable garden to deter soil-borne pests and diseases from attacking them. Strawberries are a good example here, as they are effectively an annual, needing to be divided every year. A strawberry bed that you rotate with flowers and annual herbs (such as basil or dill) is useful for avoiding soil-borne pest problems.

Perennial crops, such as asparagus and rhubarb, may well merit their own distinct areas and are not rotated like annual crops. Raspberries and blackberries, which are both perennial, are best sited permanently on a wire trellis. Avoid putting them in a huge expanding clump that can take over your garden.

Consider, too, how difficult a particular plant (or the produce it offers) is to grow. Peaches, for example, can be challenging. They are disease-prone and require lots of care and attention. Unless you are a committed gardener with time on your hands, it may be best to purchase a few organically grown fruits from a local shop.

## PLANTING THE KITCHEN GARDEN

If you have recently moved into a new home, then you will have the luxury of starting your kitchen garden from scratch. If your garden is already established, there is no need to uproot everything to grow your own produce. Gardens need not be exclusively made up of just edible or ornamental plants. You may wish to start by planting a few annual vegetables and herbs among your ornamental plants. Indeed, you can easily incorporate edible plants into the garden, even mixing fruit, vegetables and herbs in ornamental beds. This planting arrangement avoids crops grown in visually uninspiring mono-cropped rows.

If you are planting vegetables in new beds, then they can be interplanted with ornamentals and herbs. Fragrant plants such as English marigolds (*Calendula*), French marigolds (*Tagetes patula*) and oregano (*Origanum*) are excellent choices for attracting beneficial insects, and interplanting with plants such as these will help to keep pests to a minimum. Large blocks of the same vegetable are likely to attract high concentrations of pests, whereas interplanting tends to confuse and dissuade them.

If you need to remove an ornamental tree or shrub that has died or outgrown its site, consider replacing it with a fruit-bearing tree or shrub. There are many possibilities, including apples, currants, raspberries, crab apples, plums and cherries, which can all provide valuable colour and texture in the garden as well as a source of food. Apart from feeding the household, excess fruit from these trees will also provide food for a range of birds and insects.

It is worthwhile researching the eventual height of plants in the planning stages. Some will simply look out of place if they are grown in the wrong location, such as planting tall plants in front of smaller ones. Many large ones will also need some form of staking or support.

Lettuce, chives, pansies and parsley create excellent borders along the edges of raised beds. Tall plants such as dill, sunflowers, daylilies, fennel, valerian, peas and beans are best grown at the back of beds or at the centres of containers. Provide trellises and other supports where needed. Choose edible flowers such as nasturtiums and chives wherever possible because they are a natural addition to gardens and make salad bowls look and taste wonderful.

You may wish to consider an edible lawn, in which some (or even all) of the lawn is given over to a groundcover such as strawberries. Strawberries are a very attractive crop because they produce fruit for most of the summer and tolerate marginal soils and light shade. However, large patches are likely to attract pests, so they should be interplanted with strong-smelling herbs like thyme and oregano which also form good groundcover. It may be an idea to keep a permanent cover of herbs and rotate the strawberry crop on a two- or three-year cycle.

## PLANTS USED AS FENCES, SCREENS AND BARRIERS

Plants can be used in a number of imaginative ways. Instead of erecting plain wooden fencing or mesh barriers why not consider planting a living one?

Above: *Onions, with their tall stems, can be grown for their decorative appearance in ornamental beds and borders.*

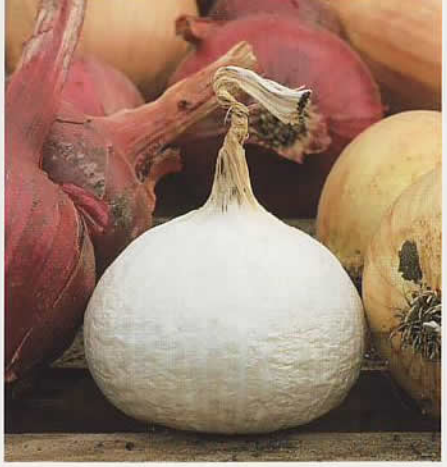
Gooseberries, raspberries or currants are readily trained along a fence and apples can be trained as an espalier cordon or fan along a wall. Climbing plants, such as hardy kiwi fruits, trailing nasturtiums, broad beans, or sugar snap peas, can all be grown over a fence or trellis work to provide an ornate screen. Hedges can also form useful and attractive edible barriers. Shrub roses, such as *Rosa rugosa*, create an attractive, but impenetrable barrier, producing large red rose hips that contain 60 times the vitamin C of an orange. The hips can be used to make tea, jam, syrup or jelly. Currants and other fruit can also be included on the sunny side.

When designing your kitchen garden, bear in mind that the garden is for everyone in the household. Hold family discussions to involve everyone in the planning and design stage. It is worthwhile taking everyone's needs and tastes into consideration when undertaking this extremely important stage of development.

Right: *Cloches and low tunnels can increase the range of early crops that can be grown in the kitchen garden.*

# CROP VARIETIES

*There is a seemingly endless array of seeds available to the home gardener. Each supplier makes claims that their variety is better than all those that went before and any others currently available. Others claim to have older, more choice varieties saved from extinction and representing a time when everything was purer and more wholesome. Personal preference usually decides the best varieties for you, but an understanding of what you can expect from the seed in a packet can be very useful.*



Above: *Onions come in a range of attractive colours and can be grown for their ornamental value in beds and borders.*

## WHAT ARE HYBRIDS?

Often when we purchase seed, we respond more readily to the picture on the front of the packet. We may not notice whether it is marked with the terms "F1" or "hybrid". A hybrid is the result of a cross between one variety with pollen from another specific variety. The breeder chooses parent varieties that will produce first generation offspring (F1 hybrids) with known characteristics. The crossing is done in a very controlled manner so that no pollen from another variety is able to pollinate the flowers. As a result, all of the plants that are grown from the hybrid seed will be genetically identical.

Hybrids may be bred to be more widely adapted to environmental stresses such as heat, cold, disease or drought than non-hybrids. They also have more uniform characteristics, making crops more predictable in their qualities. They also have "hybrid vigour" and may grow faster or be more disease-resistant than either of the parents. They may also give better yields than open-pollinated varieties. They will not breed true, however, meaning that seed collected will not produce plants that are the same as the parent (F1 hybrids). For this reason, seed cannot be saved from F1 hybrid plants by the home gardener. Seed for hybrid varieties must be purchased year after year from the seed companies or nurseries, unless you want to gamble and grow an array of offspring.

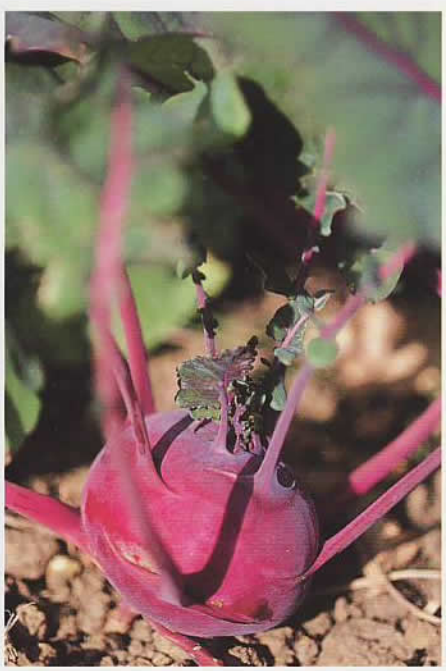
## WHAT ARE OPEN-POLLINATED VARIETIES?

Open-pollinated varieties are traditional varieties that have (in some cases) been grown and selected for desirable traits such as taste, yield or disease-resistance for many years. They often grow well in organic kitchen gardens as many were originally selected under organic conditions. These plants can mutate and adapt to the local ecosystem, as the seed is often collected and re-used by the organic gardener.

If a seed packet is labelled "heirloom", "open-pollinated" or has no special markings, then it is most likely a standard or traditional variety. The majority of lettuce, bean and pea varieties for domestic use are open-pollinated, while most cabbages, broccoli, tomatoes, cucumbers, melons and Brussels sprouts are hybrids.

Hybrid seeds can dominate the garden seed market, but open-pollinated varieties are more or less stabilized in their characteristics, remaining fairly consistent and producing seed that will grow into plants that are more or less like the parent plants. They are a little less uniform than hybrids, but the home gardener can safely collect seed and grow plants from them that will be essentially the same as the original plants. Open-pollinated varieties either self-pollinate or are pollinated by wind or insects and they usually produce viable seed.

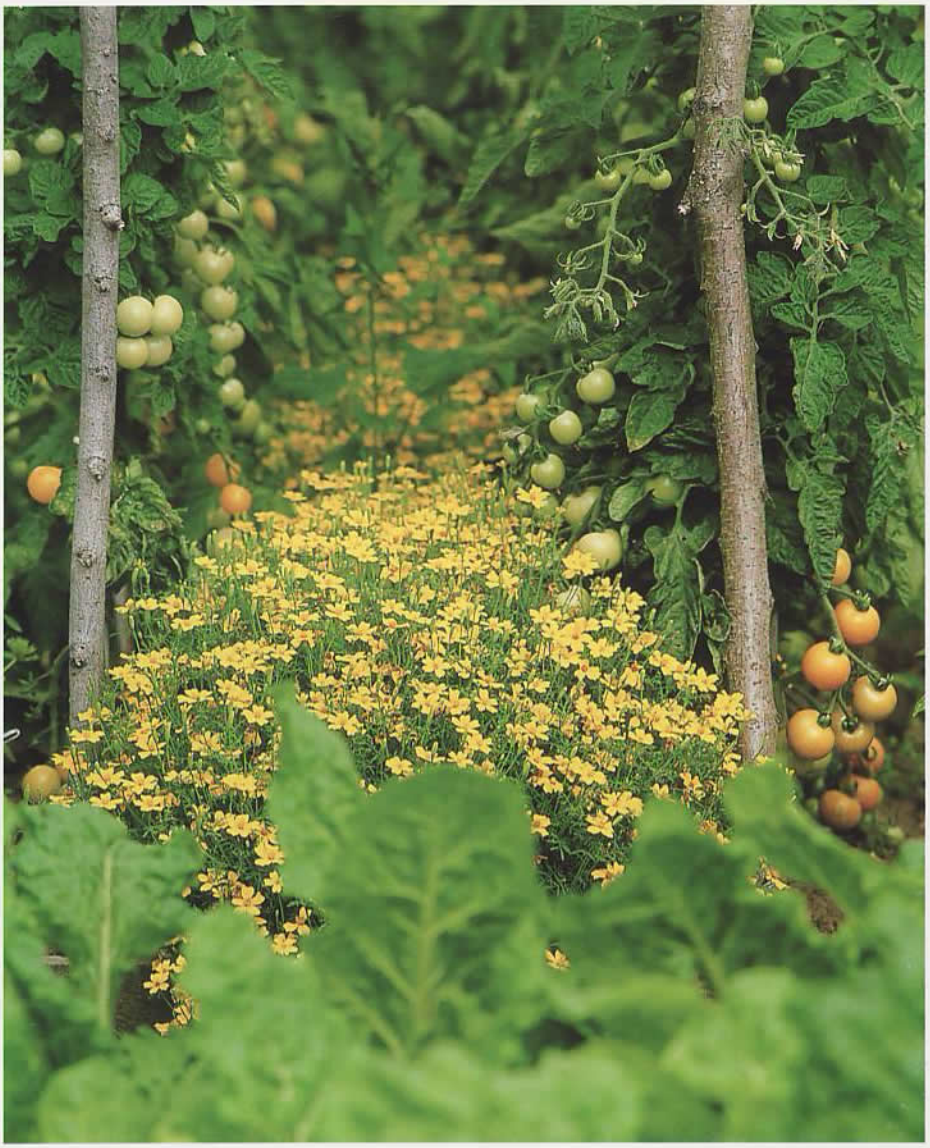
There have been various claims that open-pollinated varieties do not taste as good as hybrids. It is also claimed that they are smaller and not as uniform and, in many cases, this may be true. However, where matters of taste in varieties are concerned, the only real answer is to try them and see for yourself.



Right: *Allowing a few of your crops to flower will also provide you with seed for growing next year's crop.*

Left: *Unusual crop varieties can often be grown from seed that you have collected yourself each year. This is a striking variety of kohl rabi.*

Right: *Old varieties of tomato tend to have varying sizes of tastier fruits that crop over a long period of time.*



## WHAT ARE HEIRLOOM VARIETIES?

In the 1970s the European Community brought in regulations to encourage the breeding of new vegetable cultivars and the standardization of older ones. This resulted in a list of approved cultivars being drawn up and it became illegal to sell any cultivar that was not included on this list. It is very expensive to have a single cultivar tested in order to then register it on the list. This meant that many old cultivars were put in grave danger of being lost forever, as the funds to test each variety were not available. It was due to this legislation that HDRA, the Organic Organisation, in England, a society which was established to promote organic issues, founded the Heritage Seed Library (HSL). This seed library ensures that old or "heirloom varieties" are kept safe for posterity by distributing its seed. Although HDRA grow some of the seeds themselves, they also employ contract growers and seed guardians to make up the bulk of the seeds that are supplied.

Each year a catalogue is sent to HSL members from which they can select up to six varieties free of charge. This distribution set-up overcomes the clause of selling only approved cultivars. This service is also available to members in the United States.

The best heirloom cultivars can be traced back fifty years or longer. Many of these early varieties have been lost already, making those that remain all the more precious. A number of these cultivars have been collected and saved by families and ethnic groups dating back many years. This practice protected the genetic make-up that made each variety successful within a given environment. These base characteristics have become invaluable and the genetic strains of these vegetables are the backbone of modern disease- and drought-resistant hybrids. It is this that makes the collection and preservation of these cultivars so important.

Left: *Many heirloom varieties have been selected for the way they perform in local garden conditions, rather than for crop size or uniformity.*

# CROP ROTATION

*This is the practice of grouping and growing related plants together and rotating them around different areas of land in a regimented fashion from year to year. Rotating your crops in this way has many advantages, including helping to prevent pest and disease problems from arising in the first place. This method of gardening is fundamental to successful organic growing. It has been practised for thousands of years and developed into a system that is easy to follow.*

Above: *The secret to achieving a thriving and healthy kitchen garden is to rotate the crops on a regular basis.*

## WHY ARE CROPS ROTATED?

Continuous cropping in the same area puts both plants and soil at risk. It not only allows large numbers of soil-borne pests and diseases to build up, but, because crops require the same nutrients from the soil year after year, the practice can deplete nutrient levels. A poor infertile soil produces weak unhealthy plants, which, in turn, will be more prone to pest and disease attacks. All these problems amount to reduced yields and even complete crop failure.

When crops are rotated, the groups are divided up into closely related plants that are prone to similar pests and diseases. For example, carrots, parsnips, beetroot and potatoes are members of one group and prone to carrot fly, whereas cabbage, kale, broccoli and Brussels sprouts, which are members of another group, can be prone to clubroot and cabbage root fly. If the groups are grown in different areas on a rotational basis, it can help to prevent the establishment of soil-borne pests and diseases.

Combined with regular additions of compost and manure, crop rotation will make the soil richer, replace certain nutrients and help prevent pH imbalances that can result from repeated crops of the same type of vegetable. Companion planting will also aid a rotational plan, particularly if the species improve pest control.

## MAKING A ROTATIONAL PLAN

The basic rules of crop rotation are simple. If you are planning a four-year crop rotation, the plants you have selected are split up into five groups. Group one contains the legumes (peas and beans); group two contains the brassicas (cabbages, Brussels sprouts, broccoli, kale etc); group three contains the onion family and others (onions, lettuce, garlic, sweetcorn etc); group four includes root crops (potatoes, parsnips, carrots, beetroot etc); and finally group five houses permanent crops such as asparagus and rhubarb.

**BENEFITS OF CROP ROTATION**

There are many benefits to be gained from rotating your crops regularly.

- Prevents the build-up of soil pests and diseases
- Helps to prevent nutrient depletion from heavy-feeding crops
- Rotated crops produce higher yields
- Results in a healthier soil

The vegetable plot is then divided into five sections. The permanent crops are given a specific area and are not moved or included in the rotational cycle. The remaining four groups are allocated an area in which to grow. Every year each group is moved on to the next plot, making it four years before the crops are grown on the same area of land again; hence the name crop rotation.

If space is limited, crops can be grown on a three-year rotation. Quite simply, the crops are split into three groups, plus the permanent ones. The plant groups are divided up as before except group three is incorporated into group one.

There is no need to grow each crop in every year of a cycle. Remember that it is the vegetable groups that dictate the cropping cycle according to their soil needs and any associated problems. Rotating the crops helps provide the correct soil requirements for certain crops. For example, cabbages and the rest of the group grow well in soil that has been manured the previous autumn, whereas carrots and other root crops (not including potatoes) do not. Where carrots are to be grown, then the plot will need to be dug deeply in readiness for them.

It is important that you plan where the crops are to be every year, so that you know their position for the following year. A comprehensive cropping plan can help you to maximize the yield on a year-round basis by working out successional sowings and intercropping and catch cropping. The plan needs to include not only the crops that will be grown but also the companion plants and the soil amendments that are needed to support the best possible growth of your plants.

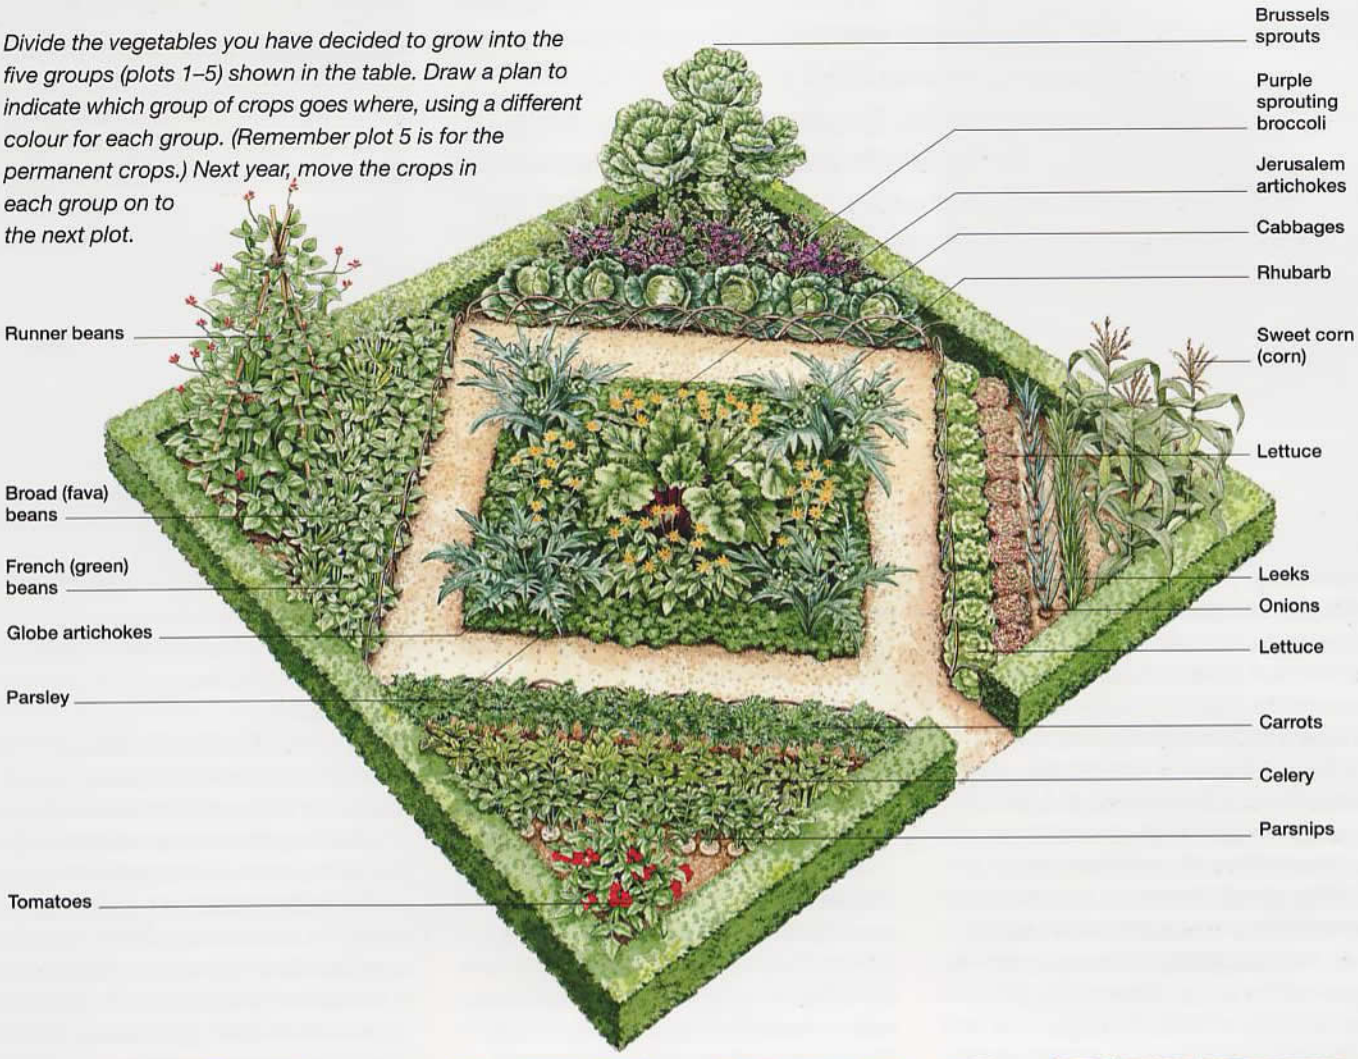
## COMMON DIFFICULTIES

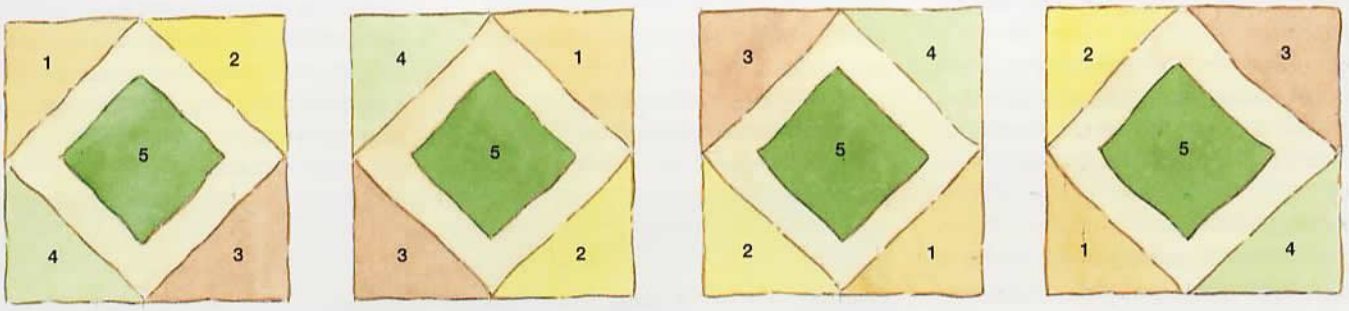
When planning the cycle, you may encounter certain problems. Careful planning will show that potatoes often take up more space in a vegetable bed than any other crop and finding enough room to grow them in their allocated area may prove difficult. Other problems you may come across include overwintering brassicas or plants left in the ground for seed collection. This is when you find that practising crop rotation in a small garden is difficult and that you may not be able to practise a strict rotation.

If space is proving a problem, consider some of the following strategies. Keep brassicas together as a group and never plant them in the same ground two years running. Keep potatoes together every year; if you have planned a lot of potatoes, move all the other members from group four into group three. Also bear in mind that some root crops, such as potatoes, are manure-friendly, while others, like parsnips, are not. Finally, alternating shallow-rooted plants like cabbages or lettuce with deep-rooted plants like tomatoes or squash will allow the plants' roots to do much of the soil loosening that would otherwise have to be done by hand. This will help to preserve the health of the soil, while causing minimal disturbance to its ecosystem.

## FOUR-YEAR CROP ROTATION

*Divide the vegetables you have decided to grow into the five groups (plots 1–5) shown in the table. Draw a plan to indicate which group of crops goes where, using a different colour for each group. (Remember plot 5 is for the permanent crops.) Next year, move the crops in each group on to the next plot.*





YEAR ONE | YEAR TWO | YEAR THREE | YEAR FOUR

**Plot 1**
Peas
Broad (fava) beans
French (green) beans
Runner beans

**Plot 2**
Cabbages
Brussels sprouts
Calabrese (Italian sprouting broccoli)
Broccoli
Kale
Radishes
Swedes (rutabagas or yellow turnips)
Turnips
Kohl rabi

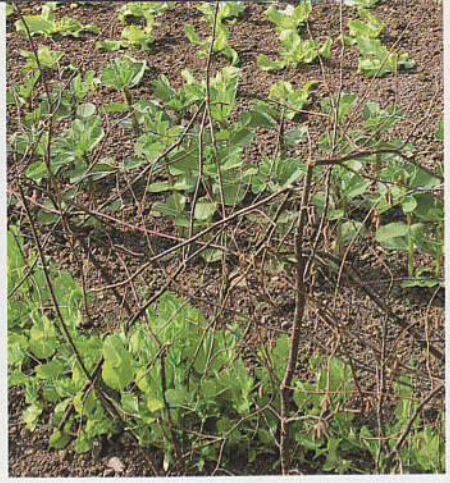
**Plot 3**
Bulb onions
Spring onions (scallions)
Shallots
Leeks
Garlic
Sweet corn (corn)
Marrows (zucchini), squashes and pumpkins
Lettuce

**Plot 4**
Potatoes
Parsnips
Beetroot (beets)
Carrots
Salsify
Scorzonera
Celery
Celeriac
Tomatoes

**Plot 5**
Rhubarb
Asparagus
Perennial herbs
Globe artichokes
Jerusalem artichokes
Seakale

# GROWING METHODS

*There are many different ways to grow your crops. You can try the traditionally practised method of sowing crops in rows or be more adventurous and grow them in blocks. The crops you have chosen to grow can be planted into a number of different types of vegetable bed: flat beds, raised or edged beds and no-dig beds. Each method and type of bed has its own advantages and disadvantages, which are described here, so choose the one that best suits your needs.*



Above: *Twiggy sticks provide an ideal support for young climbers such as peas. They also look very decorative.*

## PLANTING IN ROWS

This is the most traditionally practised and popular form of vegetable growing. It is an effective method because the spacing of the plants allows the crop to grow without excessive competition. In addition, it is relatively easy to add supports and protection such as cloches to the crops. However, this type of planting does have the disadvantage of needing relatively high maintenance. Due to the large amounts of bare earth left between the rows, the conditions are ideal for weed growth. Rows are spaced according to the optimum growth of the plants and so rows of pumpkins need to be much wider than those for carrots. Setting out rows in this way allows free movement of air along the rows. This results in fewer disease problems which can occur with more closely grown methods such as block plantings.

The rows are quite easily maintained by regular hoeing but can be wasteful of space, particularly in smaller gardens. They will produce sizeable vegetables, but this is offset by the actual yield per unit area being smaller than more intensive systems.

## BLOCK PLANTING

In this method plants are grown in squares or rectangles rather than in straight rows. Blocks of plants are grown next to each other, for example in dimensions such as five plants by five plants. The numbers of plants grown can be larger or smaller than this. Block plantings use space efficiently, producing many more plants in an area than if grown in rows.

Well-tended soil can support planting that forms a close network of foliage over the soil. The soil will retain moisture extremely well underneath the canopy. It also stops weed seeds from germinating, resulting in a less weedy environment than other growing methods. However, a close canopy of leaves can have disavantages, resulting in poor air flow and high humidity which are ideal for attracting diseases such as botrytis. During dry spells watering is essential for the health of the crops. Double check all watering that has been done because water easily runs off the dense cover of the leaves and never reaches much of the root system.

Blocks can be planted and managed at ground level or in slightly raised beds. They suit modestly sized vegetables, such as root and salad crops, that are usually grown in rows. You may have to be inventive with crop protection for early-sown crops, as cloches and low polythene tunnels do not cover the area well. The blocks are edged with permanent paths for easy access to the centre from any side so you need never walk on freshly cultivated soil. As a result, the soil does not get compacted and the closely grouped plants make maintenance and cultivation easier.

Seeding a block involves sowing the furrows thinly along close rows. For example, instead of the usual 30–40cm (12–16in) distance between carrot rows, this can be reduced to 20–25cm (8–10in). Further space savings can result from growing as much as you can vertically, rather than sprawled over the ground. Wire fencing, netting or poles and tepees take up less space than blocks of climbing vegetables. This will also keep the climbing plants dry and free of disease.

## FLAT BEDS

As the name suggests, flat beds are constructed at the natural ground level of your garden. They are the traditional way of cultivating ground for growing vegetables and are most suitable for gardens that have good soil. Flat beds will naturally raise the level of the soil, especially where organic matter is added on a regular basis as part of the cultivation regime, but the bed remains effectively at ground level. This form of gardening is relatively labour-intensive because all of the bed is cultivated, with large areas then being used as paths between the vegetables. With raised beds, there are no paths and only the growing areas are dug.

Left: *The close planting of crops in rows or blocks helps to retain soil moisture as well as reduce the growth of weeds.*

Above: *Plants such as beans can be trained over an arch in order to provide an ornamental and productive feature.*

## RAISED AND EDGED BEDS

These can be freestanding garden beds or beds with wooden or brick walls constructed several inches above the normal ground level. Raised bed gardens not only look good but they also can help solve many problems associated with soils that are difficult to manage. Problems with soil are often aggravated in urban and suburban settings, where topsoil and vegetation may have been removed or the surface level changed during building work.

Raised bed gardens improve the environment for plants by lifting their roots above poor soil. The growing medium can be amended by the incorporation of manure and/or garden compost. Soil in these beds warms up earlier in the spring, allowing the seed sown to germinate quicker than if it is grown in flat beds. Beds should be located where they will receive full sun and with protection from prevailing winds. Do not site the beds in frost pockets or where air circulation is poor.

Drainage is important. Build the beds so that the crops will not become waterlogged, as good drainage is especially important when growing vegetables. If the bed contains clay soil, incorporate sand, grit or organic matter to improve drainage. Construct the bed so that it slopes about 2cm (¾in) per metre (yard) of horizontal distance away from any structures, or away from the centre of the bed.

## NO-DIG BEDS

As the term suggests, no digging is involved in this method, which is a good way to retain good soil structure within a vegetable garden. Weeding is kept to a minimum and because the soil is not disturbed it will be alive with worms and other organisms. The bed is made on top of the ground and can be built over existing beds, lawns and even hard or rocky ground. Situate the bed in a sunny area that receives morning sun and has good drainage. It can be any size or shape, depending on your space. Start with a small bed – about 2 x 1.5m (6½ x 5ft) – but with a view to expanding in time.

When preparing the site it is not necessary to pull up the lawn or existing garden if the soil conditions are good, but if the ground is very poor, compacted or the drainage is bad, initial digging may be necessary.

Above: *Containers are an ideal way to grow a variety of crops where space is limited. These pots contain courgettes (zucchini).*

The outside wall of a no-dig bed is formed using logs, old planks, tiles, bricks or stones. Line the bed with a layer of plain wet newspaper, at least 6mm (¼in) thick. This layer should cover the enclosed area completely and overlap slightly, so as to kill off any weeds and stop new ones growing. Spread out a thin layer of hay or straw, ensuring that there are no gaps. Place a layer of good organic fertilizer, such as chicken manure, 20mm (¾in) thick, on top. Cover with a 20cm (8in) thick layer of loose bedding straw. Follow this with a 2cm (¾in) layer of good organic fertilizer and complete the bed with a top layer of garden compost, about 10cm (4in) thick. Make sure the bed is watered in well. Once it is settled you can plant out seedlings, but not seeds. Sowing seeds can begin when the bed has matured and the soil has become fine and crumbly.

No-dig beds that have been recently created are best for growing crops such as potatoes, lettuce, brassicas and cucurbits, whereas root crops grow better when the bed is mature. No-dig beds are best suited to planting vegetables in small blocks of different varieties rather than in long rows.

Left: *Vegetable beds need not be rectangular to be functional. This kitchen garden uses simple geometric shapes to provide interesting effects.*

# COMPANION PLANTING

*This is when two or more crops are grown together for the benefit of one or all. This technique creates a colourful landscape, made up of different species, which mirrors nature itself. Plants are grown together for several reasons, including to attract beneficial insects or to give off odours that deter or confuse pests. This is so different from large fields planted with only one crop, a monoculture that allows large numbers of pests and diseases to build up rapidly.*

Above: *Nasturtiums have edible leaves and flowers as well as being a colourful companion plant.*

## HOW COMPANION PLANTING WORKS

Plants have natural affinities with others of their kind. The smell of volatile oils from many plants discourages certain pests, making them excellent companion plants. A good example of this is the well-known relationship between the tomato plant and the French marigold (*Tagetes patula*). The scent of the French marigold is said to deter whitefly from entering the greenhouse and therefore avoids a whitefly attack on the tomato plant.

Plants such as yarrow (*Achillea*) and hyssop (*Hyssopus*) are just a couple of plants from a list of many that attract beneficial insects like hoverflies. The hoverflies will lay their eggs around these plants and, after hatching, the larval stage of the insect will start to eat adult aphids. So greedy are these larvae that they can eat up to 800 aphids before pupating. Many organic gardeners grow trays of single-flowered French marigolds to dot around their gardens, both in the vegetable and ornamental areas, in order to encourage these eating machines. This is both very effective and quite stunning to look at.

Certain distinct qualities of a plant have a proven benefit to others, such as fixing nitrogen in the soil. Clover in grass will fix nitrogen, offering the excess nitrogen produced to the surrounding grass which improves the yield. By the same token, others are less suited as partners. It is never wise, for example, to plant two vegetables side by side that attract the same pests, as this effectively doubles the chances of attack. It is advisable to practise crop rotation or use companion planting in between them.

### BENEFITS OF COMPANION PLANTING

A mosaic of plants offers many benefits to the organic garden, some of which are outlined below.

- Creates a colourful landscape.
- Plants can attract benefical insects.
- Plant odour can deter harmful insects.
- A variety of plants together confuses pests from locating host plants.
- Plants attract birds that prey on pests.
- Flowers attract pollinators.

## BENEFICIAL COMBINATIONS

There is little scientific evidence of these associations working, but if you talk to any organic practitioner, they will certainly provide plenty of anecdotal evidence. Tomatoes, for instance, like to be grown near basil and parsley plants. This is, of course, useful for cooks as well as gardeners. Separating rows of cabbages, broccoli or other brassicas with rows of onions has always been a popular combination, possibly due to the onion's strong scent confusing cabbage pests. Tomato plants also grow well next to cabbages and seem to deter caterpillars. Other beneficial combinations include leeks near carrots as they repel carrot flies, while Swiss chard thrives near carrots and beetroot. Never plant carrot and dill close by each other. This makes the carrots woodier and stronger-flavoured, and the dill milder and with weaker stems.

Right: *Companion plants can provide welcome splashes of colour in the kitchen garden.*

## DECORATIVE COMPANION PLANTS

Certain flowers and flowering herbs offer potential benefits for a variety of vegetables. French marigolds (*Tagetes patula*) are cited as a wonder flower by many organic gardeners and the bright flowers make a colourful companion crop. They deter many pests, and seem to spur growth in roses. They are also said to reduce the number of soil nematodes, while attracting hoverflies and their larvae which eat aphids. French marigolds are frequently planted with pot marigolds (*Calendula officinalis*).

### CROPS AND THEIR COMPANION PLANTS

While it is not an exact science, any practitioner of companion planting will tell you that individual crops have their "preferred companions". Experience is the best guide, but the list below outlines some plant combinations that work well in most situations.

**Apples** Chives, foxgloves, wallflowers, nasturtiums, garlic, onions
**Apricots** Basil, tansy, wormwood
**Asparagus** Tomatoes, parsley, basil
**Beans** Carrots, cucumbers, cabbages, lettuce, peas, parsley, cauliflower, spinach, summer savory
**Beans (broad/fava)** Potatoes, sweetcorn (corn).
**Beans (dwarf)** Beetroot, potatoes
**Beetroot** Onions, kohl rabi, lettuce, cabbage, dwarf beans
**Brussels sprouts** Nasturtiums
**Cabbages** Beans, beetroot, celery, mint, thyme, sage, onions, rosemary, dill, potatoes, chamomile, oregano, hyssop, wormwood, nasturtiums, tansy, coriander (cilantro)
**Carrots** Peas, radishes, lettuce, chives, sage, onions, leeks
**Cauliflowers** Celery, beans, tansy, nasturtium
**Celery** Tomatoes, dill, beans, leeks, cabbage, cauliflowers
**Chives** Parsley, apples, carrots, tomatoes
**Courgette (zucchini)** Nasturtiums
**Cucumbers** Potatoes (early crop only), beans, celery, lettuce, sweetcorn, Savoy cabbages, sunflowers, nasturtiums
**Kohl rabi** Beetroot, onions
**Garlic** Roses, apples, peaches
**Grapevines** Geraniums, mulberries, hyssop, basil, tansy
**Leeks** Carrots, celery
**Lettuce** Carrots, onions, strawberries, beetroot, cabbages, radishes, tagetes
**Onions** Carrots, beetroot, lettuce, chamomile, kohl rabi, courgettes
**Parsnips** Peas, potatoes, peppers, beans, radishes, garlic
**Peaches** Tansy, garlic, basil, wormwood
**Peas** Potatoes, radishes, carrots, turnips
**Potatoes** Peas, beans, cabbage, sweetcorn, broad beans, green beans, nasturtium, marigolds, foxgloves, horseradish, aubergine (eggplant)
**Pumpkin** Sweetcorn
**Radishes** Lettuces, peas, chervil, nasturtium
**Raspberries** Tansy
**Spinach** Strawberries
**Squash** Sunflowers
**Strawberries** Borage, lettuce, spinach, sage, pyrethrum
**Sunflowers** Squash, cucumber
**Sweetcorn (corn)** Broad beans, potatoes, melons, tomatoes, cucumber, squash, tansy
**Tomatoes** Asparagus, celery, parsley, basil, carrots, chives, marigolds, foxgloves, garlic, sweetcorn
**Turnips** Peas, nasturtiums

Left: *Foxgloves (*Digitalis*) make excellent companion plants for growing under apple trees.*

White alyssum (*Lobularia maritima*), by reseeding frequently, helps to break up the soil and adds to its organic content, while chrysanthemums reduce nematodes, making for healthier soil. Mint almost always works with various types of squashes and brassicas to aid plant growth, although it can become invasive. Tansy (*Tanacetum vulgare*) is said to repel ants, aphids and plant beetles although this, too, can become invasive if not regularly checked.

Chamomile (*Chamaemelum nobile*) is known as the "plant doctor" by some organic gardeners because of its alleged ability to encourage other plants to increase their production of essential oil, making plants such as rosemary and lavender taste and smell stronger. Chamomile is easy to grow and looks beautiful anywhere, although it should be kept well trimmed to avoid a straggly look. It is also thought that chamomile can help to activate the composting process if it is added to the compost heap.

Lavender (*Lavandula*) is a general insect repellent and makes an excellent small hedge. It is a great addition to the garden, attracting bees and numerous white and blue butterflies.

Plants that produce berries such as cotoneaster and the rowan tree (*Sorbus*) will attract birds into the garden. Birds, in turn, eat many pests, such as protein-rich aphids, caterpillars and various flies. Thrushes are the unsung heroes of the garden because they decrease the snail population quite considerably.

Be prepared to experiment before committing to a companion species. Nasturtiums have been cited as an effective aphid control, although many wonder if they do this by attracting all the aphids to themselves. What works in one area may not always work elsewhere and experimentation is the key to success in this interesting yet uncertain area of organic gardening.

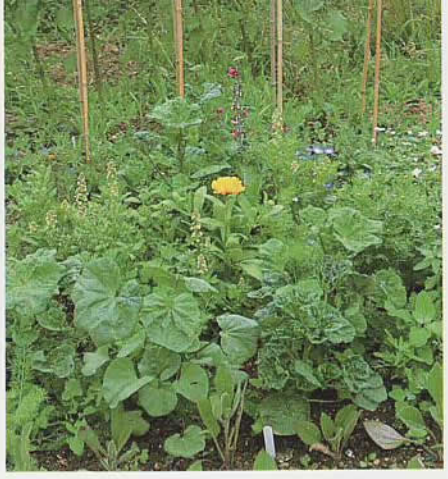
### CROPS AND THEIR ANTAGONISTS

Some plants are highly antagonistic to one another. You should always avoid planting the following combinations.

**Asparagus** Onion and potato
**Beans** Chives, fennel or garlic
**Carrots** Dill
**Carrots, cauliflower or potatoes** Tomatoes
**Peas** Onion, garlic and shallots
**Potato** Pumpkin and summer squash

# MAKING THE MOST OF YOUR SPACE

*There are three basic growing techniques that you can use to make the most of your space. These are known as intercropping, catch cropping and successional sowing. By adopting the latter two practices, you will extend the cropping season instead of harvesting a crop all at once. You will also make use of the available space, therefore increasing yields. All that is needed is careful planning to work out which crops to sow and when.*



Above: *Close planting in blocks makes the most of available space and allows more crops to be raised in a season.*

## INTERCROPPING

This kitchen-garden technique increases productivity and also helps to keep the numbers of weeds down. It refers to the practice of planting a fast-growing crop, such as carrots, radishes and lettuce, between main crops that are slower growing. These include vegetables such as cabbages, peas and potatoes.

Intercropping involves harvesting the quicker-growing crop first before the slower-growing one achieves total foliage cover of the soil or shades out the area. A good example of intercropping is to grow a crop of spring onions or lettuce between tomatoes. Similarly, spinach or radishes can easily be planted out early between sweetcorn or, alternatively, radishes can be planted between cabbages.

Intercropping can also be used to increase productivity. It ensures that no space is left unused and makes the most efficient use of light, nutrients and moisture. It will also reduce the amount of weeds in the vegetable patch by maintaining a continuous plant canopy over the soil.

One slight variation on the theme is to combine the benefits of a green manure with a crop. This can be useful in the case of winter crops because the green manure doubles up as a cover crop, protecting the soil from erosion and leaching as well as stabilizing soil temperatures. If a leguminous green manure is planted in late summer or early autumn in a bed along with leafy crops such as Brussels sprouts, it can provide nitrogen throughout the remaining growing season. It will also provide a boost for early crops that will be planted out after the green manure crop has been dug into the soil. While intercropping requires careful planning, it can increase the productivity of even a relatively small vegetable plot.

## CATCH CROPPING

This technique is when fast-maturing vegetables, such as radishes and lettuce, are grown in an area of ground that has just been cropped and has a vacancy until the next crop is either sown or planted. The sowing of the catch crops can be done in between the main ones or after harvesting at the end of the season if there is time. It is important to know how long a crop takes to mature when planning catch cropping so that you do not sow anything that takes too long to mature in between the main crops.

Left: *Successional sowing in rows allows the same space in the vegetable plot to be kept productive throughout the growing season.*

### ADVANTAGES OF INTERCROPPING AND CATCH CROPPING

Making the most of your space is not only productive, but it also has environmental advantages.

- Suppresses weed growth in the kitchen garden
- Increases the productivity of the vegetable patch
- Planting green manures enriches the soil with nitrogen
- Helps to protect against the erosion of the soil
- Helps prevent leaching

Above: *The close spacing of rows and successional sowing of new rows allows the maximum use of space on your plot.*

## SUCCESSIONAL SOWING

This is the practice of sowing the seeds of fast-maturing vegetables at regular intervals several times during the growing season. This practice will ensure that you have a continuous supply of crops such as lettuces, carrots and spinach throughout the season. Successional sowing is also useful where crops are sown directly outdoors early in the season where they may be prone to frost damage. Early crops such as lettuce and radish can be sown under the cover of, for example, a cloche where they will begin to develop earlier than would otherwise be possible. Subsequent sowings outdoors will mature later, thus extending the growing season for harvesting.

Gardeners with small plots can use this method by sowing only a half a row at any one time. This process is then repeated a week or so later, with further sowings as often as you like. This way you will have fresh vegetables for several weeks and will avoid a sudden glut.

Above: *Sweetcorn (corn) is a late-maturing crop that can be intercropped with fast-growing, early salad crops. This enables you to make the most of your growing space.*

### FAST-GROWING CROPS SUITABLE FOR INTERCROPPING AND CATCH CROPPING

Use all the available space by sowing vigorous growing crops in between rows of the main crops. The list below shows the time it takes some fast-growing crops to mature.

| | |
|---|---|
| **Carrots** | 9 to 20 weeks |
| **Endives** | 7 to 13 weeks |
| **Lettuce** | 4 to 14 weeks |
| **Radishes** | 4 to 8 weeks |
| **Rocket (arugula)** | 3 to 5 weeks |
| **Salad leaves** | 4 to 14 weeks |
| **Spinach** | 5 to 10 weeks |
| **Spring onions** | 8 to 10 weeks |

### CROPS SUITABLE FOR SUCCESSIONAL SOWING

The technique of successional sowing can ensure a continuous supply of fresh vegetables. It also increases the productivity of the garden and avoids harvest gluts.

| | |
|---|---|
| **Beetroot** | Spring to summer |
| **Broccoli** | Spring to summer |
| **Cabbages** | Spring to summer |
| **Carrots** | Spring to summer |
| **Endives** | Spring to summer |
| **Kohl rabi** | Winter to summer |
| **Lettuce** | Winter to summer |
| **Parsnips** | Winter to spring |
| **Peas** | All year round |
| **Potatoes** | Spring |
| **Radishes** | Winter to summer |
| **Salad leaves** | Spring to autumn |
| **Salad rocket** | Spring to autumn |
| **Spinach** | Spring to summer |
| **Spring onions (scallions)** | Spring to autumn |
| **Swedes** | Spring to summer |
| **Swiss chard** | Spring to summer |
| **Turnips** | Winter to spring |

# SOWING IN THE OPEN

*There can be nothing more satisfying than sowing seeds and watching in anticipation for them to germinate. Watching the seedlings grow in your kitchen garden, making it come alive with leaves, flowers and insects is a fantastic experience. One of the drawbacks of sowing out in the open is that you are at the mercy of the weather, but you can manipulate your garden environment by using cloches, small plastic bottles and polythene tunnels to increase your chances of success.*

Above: *A dibber (dibble) is a very helpful tool to use when you are transplanting seedlings outside.*

## SITE REQUIREMENTS

If you are a novice kitchen gardener, be assured that sowing seed is easier than you may think. In order to germinate successfully seeds need water, air, a suitable temperature and a place into which they can root in order to support the top growth that will follow. For this reason, good soil preparation is everything to organic success. Most garden soils are able to supply all the necessary elements and only slight modifications are usually necessary. However, it is important that the ground is prepared in a way that will enable the seed to germinate evenly and grow in a uniform environment. The prior preparation of a seedbed can provide the seed with the environment that it needs and has the added bonus of making the task of seed sowing easier.

Preparing a seedbed is simple. Following cultivation, the ground is levelled using a rake, held at a shallow angle, to break down any large clods. The art of levelling is to keep the rake angle shallow and move the high spots over into the low spots with even strokes. Hold the rake firmly at the rear and let the shaft run smoothly through the front hand. All stones and large objects, including organic matter such as twigs or previous crop debris, should be removed by combing them out with the teeth of the rake, while holding the tool in a near vertical position. The soil is then firmed with light treading. A light shuffle across the bed is best. Once firmed, lightly rake the soil again at a shallow angle to produce a light "fluffy" surface that runs freely through the teeth of the rake. This is the perfect environment for sowing and growing seeds.

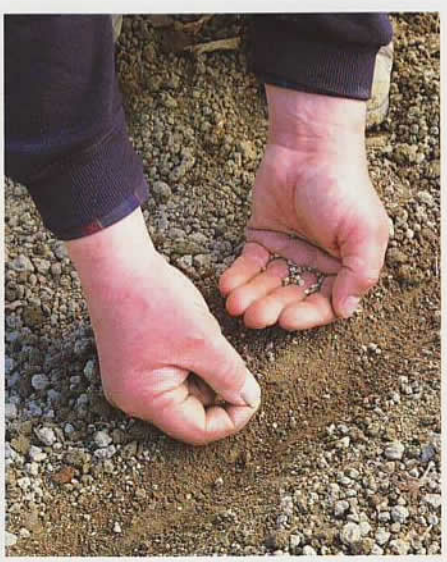
## SEED REQUIREMENTS

The conditions that seeds require to germinate are easy and straightforward to create. A well-aerated moist soil environment is almost all that the seed needs. Most seeds will germinate quite successfully once the temperature gets above 7°C (45°F). Seeds carry their own food supply that provides them with everything they need for those first crucial days following germination. Once the plant begins to establish and grow, it needs soil-borne nutrients. This means that the soil in which it is growing needs to be of the right fertility for the plant. Poorer soils can benefit from the addition of a base dressing with fish, blood and bone prior to sowing to give the boost that the developing plant needs, although loamier soils need only be properly dug and prepared to support germination.

## SOWING SEEDS OUTDOORS

**1** *Set a tight string line where you intend your crop row to be and make a shallow drill with the edge of a swan-necked hoe.*

**2** *Water dry soil using a watering can fitted with a fine rose about an hour before sowing and allow to drain.*



**3** *Sow the seed thinly along the length of the row. Larger seed may be station sown at regular intervals.*

Some seeds can benefit from being soaked for a short period in tepid water just before planting to help them take on the water they need for germination. This is especially true of beets, but other large seeds also benefit from this treatment.

### SOWING IN ROWS

Seed is usually sown in rows. Using a tightly drawn garden line as a guide, draw the corner of a swan-necked hoe along the line to create a shallow drill of about 1–2cm (⅜–¾in) depth, depending upon the seed's individual requirements. Dry ground can be watered after the drill is made. Sow the seed thinly and mix fine seed with silver sand to make it easier to distribute evenly. Mark the end of each row with a label before moving on to the next.

### STATION SOWING

Seeds of larger growing plants, particularly those with seed that is large enough to handle, benefit from station sowing. This involves sowing two or three seeds at intervals that will be the eventual crop spacing. If all three germinate, then the two weaker ones are removed or transplanted to gaps where none has germinated.

### WIDE ROWS

Certain seeds, particularly peas and beans, benefit from being planted in wide rows. Two rows are effectively station sown at

Left: *Station sowing is ideal for larger seeds or seedlings that resent disturbance. Use a marked stick to set the spacing of the seed.*

once, one on each side of a drill that is 15cm (6in) across. The drill is made with the flat of the hoe and after sowing the soil is carefully raked back. Make sure that you do not disturb the seeds from their stations.

### BROADCASTING (BLOCKS)

Broadcasting is an ancient method of seed sowing that was used to sow large areas of crops. It involves a "broadcasting" action that separates the seed to an even spacing. The easiest way to do this in small vegetable plots is to split the seed into two halves, mixing small seed with fine sand. Scatter the seed carefully, letting it run from your hand in even arcs as you move your arm from side to side. Sow each half of the seed at a 90-degree angle to the other, thereby assuring an even distribution. Gently rake the seed in once sown and lightly water if needed.

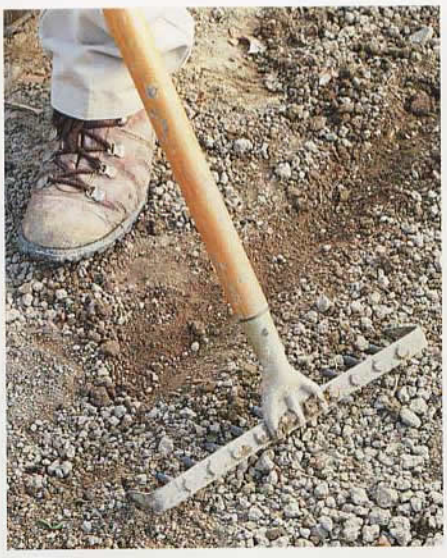
### PROTECTING SEEDLINGS

Seedbeds, with their fine "fluffed" earth, act as magnets to birds and animals. Some may take the seed from the ground, but, in truth, most will find it more attractive as a dust bath or litter tray. Once the seedlings emerge, however, some birds find them irresistible. They must be kept out with some form of barrier. One of the easiest methods is to form a low tunnel of chicken wire, supporting this on hoops. For larger areas, a series of stakes in the ground can be covered with netting to keep birds at bay. Sticks with thread or string stretched between them are also effective, but less easily removed for you to tend the crop.

### LABELLING

When you sow a row or area of seeds, label it straightaway. Re-usable plastic labels are the best option. Each label should have the name and variety of the plant sown. You may also wish to record the sowing date and if the seed was pre-treated.

**4** *Place a label at the end of each row, showing the crop name, variety and the sowing date, before you start a new one.*



**5** *Gently cover the seed using a rake. Take care not to disturb or move the seed in the row when you cover it.*

**6** *Alternatively, seed can be covered using a soil and potting mix. This is useful on heavy soils and avoids capping (surface hardening).*

# SOWING UNDER GLASS

*Sowing seed under glass extends the growing season and enables you to raise tender crops that only survive outside in warmer months. It is also ideal for rapidly establishing plants to use as catch crops and as early companion plants. In short, it offers variety and choice for your cropping regimes. Plants raised under glass can be grown on until they reach a size where they are better able to resist pest attack. They can also be planted out at their final spacing, thereby avoiding thinning or gaps in rows.*

Above: *A propagator is a useful piece of equipment for raising your seed in ideal growing conditions.*

## HEAT REQUIREMENTS

Most seeds have a preferred temperature range within which they will grow. A heated greenhouse, a conservatory or even a warm living room will often provide this, although seeds needing a constant high temperature may need a propagator. Such seeds are mercifully rare among vegetables, although cucumbers, tomatoes and peppers are good examples of crops that will benefit if they are first started off in a propagator.

## CHOICE OF CONTAINER

There are a variety of containers that may be used to sow seed under glass. The most common form is the plastic seed tray which has now largely replaced the wooden seed tray. Although more attractive, wooden trays are difficult to keep clean and may harbour plant diseases. Plastic trays can be made of durable polyurethane or sometimes a more flimsy, thin, moulded plastic which is intended for single use. They are available in a variety of sizes, although small 9cm (3½in) pots may be more suitable when you are raising only a few plants.

Modular seed trays are another option. These are made up of individual cells, and a single seed is sown into each one. Seeds that are sown in these trays have the advantage of not suffering any root disturbance when they are planted out in their eventual position. The same is true of some biodegradable pots, which are formed out of paper and coir. These are better (environmentally speaking) than those made from peat, but any recycled material used for these trays is acceptable in the organic kitchen garden.

Inventive recycling can also provide an array of useful sowing containers. Re-using plastic cups, vegetable packing trays and

Left: *Many propagators have ventilators on the top in order to aid the flow of fresh air to the seedlings.*

any other throw-away items that might otherwise end up on a landfill site are all possibilities worth exploring. Old plastic bottles make good individual propagation cowls for small pots and plastic bags can also be used to cover the tops of pots and trays in order to maintain humidity.

## PROPAGATORS

These are, in effect, mini-hothouses that help to keep the seed in a warm, moist, stable environment both above and below the soil line. Expensive propagators involve the use of electric soil-warming cables and some have thermostats to control the soil temperature. Many are designed for use in the greenhouse, but some models are narrow enough for use on a windowsill inside the house. Alternatively, instead of buying the whole propagator, you can purchase a heating mat on which the seed trays can stand in order to receive heat at the bottom. This system has the advantage of being mobile and easily moved about from area to area. Another cheaper method is to buy soil-heating cables to bed into sand. The seed trays sit on the bed of heated sand to receive an even supply of bottom heat.

## AFTERCARE OF SEEDLINGS

Once seeds begin to germinate, they can be moved gradually into a less humid environment. The trays are freed of plastic covers, or the propagator vents or lids are opened and, after a few days, the lid is removed completely. As soon as the seedlings reach a size at which they can be handled, they are carefully pricked out into individual pots or larger boxes and trays. Always handle the seedlings by the leaves,

Above: *Modular trays are ideal for planting large seeds and avoid disturbance to roots when planting out or potting on.*

Above: *Individual pots can be used for large seeds. Plant two seeds per pot and remove the weaker seedling.*

## SOWING IN TRAYS

**1** *Fill a seed tray with propagation potting mix that has been thoroughly mixed. Fill the tray to overflowing and do not firm in the potting mix.*

**2** *Using a straightedged piece of board, level the surface of the potting mix by carefully moving the board across the top of the tray.*

**3** *Water the tray and leave to drain for about 20 minutes before sowing the seed on the moist surface of the potting mix.*

**4** *Larger seed can be placed on the surface of the potting mix at regular intervals. Regular spacing will prevent overcrowding.*

**5** *Once the seed has been sown, use a sieve to cover the surface with a fine layer of potting mix.*

**6** *Do not cover the seeds of plants that require light for germination. Always check the growing requirements of plants before sowing the seed.*

gently lifting each one from beneath, using a dibber (dibble). Never hold them by the stems because this can cause a great deal of damage to the developing plant. They should be spaced at least 5cm (2in) apart to allow for subsequent development. Water the transplanted seedlings with a fine upturned rose attached to a watering can that has been filled with water overnight, thus bringing it up to room temperature and not giving the transplants a shock of cold water. Keep the seedlings on a warm and sheltered windowsill or in a greenhouse or conservatory. A constant temperature will promote healthy growth.

Above: *Growing vegetables in pots under glass can extend the growing season and also provide a colourful greenhouse display.*

### HARDENING OFF

Plants that have been grown in a greenhouse cannot be put straight outside because their growth is too soft to withstand the cold. They must be gradually hardened off and acclimatized to outdoor conditions. The young plants are hardened off by moving them from the greenhouse and into a cold frame, planted out under cloches, low polythene tunnels or horticultural fleece. Open up the cloches and cold frames or remove the fleece during the day and replace at night for a week or two before planting out or removing the cloches completely. Remove low polythene tunnels after a couple of weeks depending on the weather conditions. If these are severe, leave in place for longer.

Above: *Watering from below by pouring the water into the base of the seed tray will prevent damage to newly emerging seed.*

# THINNING AND TRANSPLANTING

*Thinning seedlings not only allows the plants left in the soil to develop and mature into their natural shape and habit, but it is an essential process for good plant health. Thinned seedlings can be transplanted into bare areas or more often special seedbeds are set up or crops are grown under glass and the whole batch of seedlings are transplanted into their final destination within the vegetable garden.*

Above: *Growing plants from seed is one of the most satisfying ways of producing new stock for the kitchen garden.*

## WHY THIN SEEDLINGS?

All plants need space to develop and grow. Plants that are growing too closely compete not only for space, but also for light, water and important nutrients. In addition to this competitive stress, they also become prone to a variety of fungal diseases, as the air is not able to move around them. Thinning the seedlings helps to counteract these problems and will result in larger, stronger and healthier plants.

## HOW TO THIN SEEDLINGS

Thinning is essentially two processes in one. Firstly, you are removing all the plants that are excess to requirements and at the same time you are selecting the biggest, healthiest and strongest plants that will be retained to form the crop.

Before starting to thin, dry ground must be watered, preferably the night before you intend to thin. A measuring stick, marked with the appropriate crop distance, can be used to show the approximate position of the individual plants. Remove all the plants in between each of the markers, selecting the healthiest plant at or near the mark on the stick. If there are no plants at the marked point, then you can transplant one of the seedlings that is excess to requirements into this position. When you are removing the excess plants, place a finger on the soil at either side of the seedling that is being kept. This protects it from root disturbance. Once you have finished, water the remaining seedlings with a fine rose on a watering can to re-firm the soil around the plants. The seedlings that have been removed can be put on the compost heap.

Left: *Seedlings grown elsewhere in the garden can be lifted and replanted in their eventual positions. This method is good for crops that need wide spacing.*

Above: *Rows of seedlings are often too crowded and need to be thinned when the plants are young.*

Avoid thinning with this method on hot dry days or in windy conditions, as the remaining seedlings may become water-stressed if their roots are disturbed. The alternative, in this case, is to snip off the seedlings at ground level with a pair of sharp scissors, thereby avoiding root disturbance.

### THINNING DISTANCES

The following measurements are the distances that need to be left between thinned seedlings.

| | |
|---|---|
| **Beetroot** | 7.5–10cm (3–4in) |
| **Broad beans (fava beans)** | 23cm (9in) |
| **Carrots** | 7.5cm (3in) |
| **Dwarf French beans (bush green beans)** | 20cm (8in) |
| **Florence fennel** | 25cm (10in) |
| **Kohl rabi** | 20cm (8in) |
| **Lettuce** | 23cm (9in) |
| **Parsley** | 15cm (6in) |
| **Peas** | 5cm (2in) |
| **Parsnips** | 15–20cm (6–9in) |
| **Radishes** | 2.5–5cm (1–2in) |
| **Runner beans** | 25–30cm (10–12in) |
| **Salsify** | 15cm (6in) |
| **Scorzonera** | 15cm (6in) |
| **Spinach** | 15cm (6in) |
| **Spring onions (scallions)** | 5cm (2in) |
| **Swedes (rutabaga or yellow turnip)** | 30cm (12in) |
| **Swiss chard** | 30cm (12in) |
| **Turnips** | 15–20cm (6–8in) |

## TRANSPLANTING SEEDLINGS

**1** *Water your row of seedlings at least an hour before transplanting and preferably the night before if no rain has fallen.*

**2** *Using a fork to loosen the soil, gently lift the seedlings. Take care to handle them by their leaves and never touch the stems.*

**3** *Using a tight line, straight edge or notched planting board, replant the seedlings at the appropriate spacing for that crop.*

**4** *Gently water the seedlings immediately after sowing. Never let roots dry out at any stage during transplanting.*

### TRANSPLANTING SEEDLINGS

The most common way of transplanting seedlings involves planting container-grown plants into open ground. Early vegetable crops can easily be raised in this way. The other method is to raise seedlings in open ground near to where they are to be planted out. Transplanting outdoor seedlings means that a smaller area of the vegetable plot is needed for sowing and, in consequence, a smaller seedbed is required. Transplanting seedlings is a good way of growing plants such as lettuce that are to be used in catch-cropping beds or where plants are to be planted out in no-dig beds.

The ideal time for transplanting outdoor seedlings is during damp overcast weather because this helps to prevent the seedlings' roots drying out. As is the case when thinning the plants, the seedlings will need watering the evening before. It is best to dig up only a few plants at a time, discarding any that are weak, damaged or appear to be sick. Seedlings can be placed in a plastic bag to maintain humidity around them while they are out of the ground.

A garden line can be set out in the vegetable patch in a similar manner to the way in which it is placed for preparing a seed drill. The position of the plants can then be determined using a measuring stick. Use a dibber (dibble) or thin trowel to plant the seedlings, firming lightly around the base before moving on to the next transplant. Once the row is completed, it is important that you water them in.

For catch cropping or planting among other plants, the surrounding crop may well determine the spacings between the transplants, although the procedure remains exactly the same.

### COMMON PLANTING DISTANCES

Always allow the correct spacing between crop plants so that they will grow into healthy specimens.

| | |
|---|---|
| **Asparagus** | 30–38cm (12–15in) |
| **Aubergines (eggplant)** | 60cm (24in) |
| **Broccoli** | 60cm (24in) |
| **Brussels sprouts** | 50–75cm (20–30in) |
| **Cabbages** | 30–50cm (12–20in) |
| **Calabrese (Italian sprouting broccoli)** | 15–23cm (6–9in) |
| **Cauliflowers** | 50–75cm (20–30in) |
| **Celeriac** | 30–38cm (12–15in) |
| **Celery** | 23–30cm (9–12in) |
| **Courgettes (zucchini)** | 60cm (24in) |
| **Cucumbers** | 60cm (24in) |
| **Garlic** | 15cm (6in) |
| **Globe artichokes** | 75cm (30in) |
| **Jerusalem artichokes** | 30cm (12in) |
| **Kale** | 60cm (24in) |
| **Leeks** | 15cm (6in) |
| **Marrows (zucchini)** | 60cm (24in) |
| **Onion sets** | 10cm (4in) |
| **Peppers** | 45–60cm (18–24in) |
| **Potatoes** | 30–38cm (12–15in) |
| **Pumpkins** | 90–180cm (3–6ft) |
| **Rhubarb** | 75–90cm (30–36in) |
| **Runner beans** | 25–30cm (10–12in) |
| **Seakale** | 30cm (12in) |
| **Shallots** | 15–18cm (6–7in) |
| **Sweetcorn (corn)** | 30cm (12in) |
| **Tomatoes** | 60cm (24in) |

# AFTERCARE

*The aftercare that your crops require is essential to ensure healthy plants that produce high yields. There are a number of different techniques that are listed below to help you on your way. Just remember that the more effort you put in then the better they will taste. As well as judicious watering and feeding, you will also have to weed the vegetable plot and provide some form of plant protection and support. But the reward of such care and attention is delicious home-grown produce.*

Above: *Regular cropping of vegetables such as this ruby chard will encourage the development of new growth.*

## WATERING

Vegetables need watering if there is no significant rainfall. This is especially true when the crops are young and only have shallow roots. Having a soil that is rich in organic matter is an advantage because it conserves water in the soil, particularly if the soil is sandy. You can enrich the soil by digging in organic matter, growing green manures or by continuous mulching.

If you have a large garden, mulching around the crop with straw, farmyard manure, garden compost or another similar substance can help to limit water loss. When you water, it is best to give the plants a thorough soaking, allowing the water to penetrate deeply. Giving a light watering will just encourage shallow surface roots that are easily damaged by prolonged drought. Prolonged dry periods also encourage plants to bolt, thus ruining the crop.

Certain plants such as cabbages and lettuces are naturally shallow rooted, whereas others such as tomatoes and squash are naturally deep rooted. Shallow rooters especially benefit from mulching and may need watering often in hot summers.

## FEEDING

This is generally only necessary for heavier feeding plants such as pumpkins and marrows, but can provide a tonic for any crop during the growing season. Specific nutrient deficiencies are rare in the garden if a regular crop rotation and soil enrichment programme is followed, but if specific shortages are noticed, they must be countered immediately. Good liquid feeds can be made in your back garden. Try making compost tea or "worm liquid", as these are an excellent choice for actively growing plants.

Above: *The effort you put into protecting and caring for your crops will be rewarded at harvest time.*

Apply these feeds once every week or two. Many plants are given their main feed annually. This type of feeding is normally applied to fruit trees and bushes in the spring and is best applied in the form of a slower-release fertilizer such as bonemeal.

Above: *The careful harvesting of crops is essential if they are to store well. Here, carrots are being lifted with a garden fork.*

Above: *The regular harvesting of peas and beans will help to extend the length of the harvest period.*

## WEEDING

Check your plants regularly and try to keep them as weed-free as possible. Remember that weeds compete with your plants for light, space, water and nutrients. It is better to weed a little and often than to weed irregularly. Even areas that have been mulched or have close cropping regimes need regular checks and weeds removed.

## PLANT PROTECTION

Pests and diseases come in many different forms. Over time you will learn which specific problems your garden is prone to. Keep a yearly notebook of all the things that affect your crop each season, noting what control measures you used and how effective they were. In time you will have a record of how and when to manage pests and other problems in your own garden.

Above: *Taller plants and climbers will need some form of support. Canes or sticks with twine tied between them provide ideal temporary supports.*

## PROVIDING SUPPORT

Plants may need supporting, especially climbers such as peas and beans. This support must begin at an early age, using twiggy pea sticks or hazel sticks, both of which can look ornate. Bamboo canes can be used for a host of climbing plants, but it is more ethically correct to use local materials rather than to use a product that has been transported thousands of miles. Squashes can be grown up fancy supports made from stakes and strong string or rope, making a curious garden feature. Other plants such as globe artichokes and Florence fennel can benefit from individual supports for their stems.

## HARVESTING AND STORING

When harvesting, it is tempting to pick the good specimens and leave the rest, but remember to pick and compost poor or rotten ones as well as the best of the crop. Diseased or damaged crops can begin to rot and may infect the remaining harvest.

Freshly picked vegetables are higher in nutritional value than stored ones. So, during the growing season, pick what you need and store the surplus. Choosing when to pick a certain vegetable is a matter of taste. Some prefer to pick produce such as beans when they are young, small and succulent, whereas others prefer the beans to be more mature.

Crops can be stored in a number of ways. Root crops can be left in the ground in all but the coldest winters, lifting them as they are needed. Some crops, such as parsnips, actually develop a better taste after they have been subjected to frost. Alternatively, root crops can be stored in a cool dark place. They should be cleaned and stored in sand and a sterile organic substance such as coir, untreated sawdust, fine leaf mould, fine bark or sterilized soil.

Store other vegetables on shelves or boxes, ensuring that they do not touch. Onions and garlic are best kept in open sacks or in strings. Cabbages can be kept in nets until needed for up to two to three months. Other brassicas such as Brussels sprouts and swedes are best kept outside in the ground, harvesting them as needed.

Freezing is another storage option. Some vegetables, such as asparagus, beans and cauliflowers, are best blanched in boiling water for a couple of minutes before freezing. Alternatively, you can cook the vegetables and then freeze them, as is the case for marrows and Jerusalem artichokes.

Above: *Marrows and pumpkins are easily stored in trays that should then be kept in a cool dark place.*

Above: *Store root crops such as carrots in a cool dark place and cover them in sterile sawdust, leaf mould or coir.*

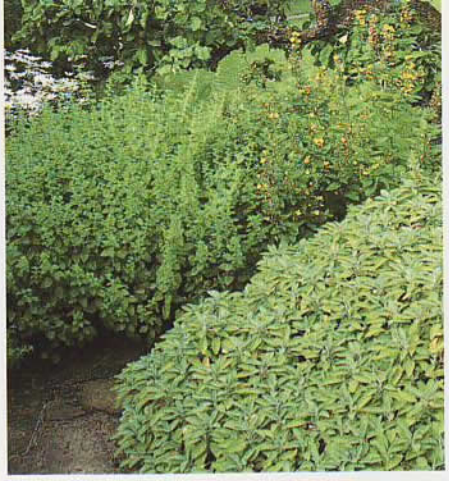
### CROPS FOR STORING OVER WINTER

Harvest time often brings the problem of a crop glut. Storage can enable you to enjoy this bounty for longer.

**Asparagus** Best consumed fresh. Cook or blanch before freezing
**Aubergines (eggplant)** Cook before freezing
**Beetroot (beets)** Shelf storage or pickling
**Broad (fava) beans** Freezing or drying
**Brussels sprouts** Freezing. Leave on plant until needed
**Cabbages** Freezing or shelf storage. Leave in ground in mild conditions
**Carrots** Leave in ground in mild conditions. Shelf storage
**Cauliflowers** Blanch before freezing. Shelf storage if hung upside down in dark and misted
**Celery** Cook before freezing. Limited shelf storage
**Courgettes (zucchini)** Cook before freezing. Limited shelf storage
**Dwarf French beans (bush green beans)** Freezing
**Garlic** In sacks or strung
**Kale** Harvest through winter
**Kohl rabi** Leave in ground if mild or protected, medium shelf storage
**Leeks** Freezing, leave in ground in mild conditions, shelf storage
**Marrows (zucchini)** Cook before freezing, shelf storage
**Onions** In sacks or strung
**Parsnips** Leave in ground until needed or late winter
**Peas** Freezing or drying on plant
**Peppers** Blanch before freezing. Pickle or dry
**Potatoes** Store in paper sacks once cleaned and dried
**Pumpkins** Cook before freezing. Good shelf storage if fully ripe
**Rhubarb** Cook before freezing
**Runner beans** Freezing
**Shallots** In sacks or strung
**Spinach** Cook then freeze
**Swedes (rutabaga or yellow turnip)** Leave in ground until needed (may go woody by late winter)
**Sweetcorn (corn)** Freezing or pickling
**Tomatoes** Cook before freezing. Pickle
**Turnips** Leave in ground until needed

# GROWING HERBS

*Herbs are valued for their culinary, medicinal, decorative and aromatic properties. They come in a diverse range of sizes, shapes and habits, ranging from ground-creeping thyme through to the tall architectural stems of angelica. The choice of herbs is so great that there is always something to offer a gardener with only a window box, hanging basket or a small space. A herb garden offers a treat for the senses and these fragrant plants are also easy to grow in the organic garden.*



Above: *Herbs are easy to grow given the right growing conditions. They provide an attractive, often fragrant, display.*

## WHERE TO GROW HERBS

Herbs can be grown in a range of settings, such as custom-designed herb gardens and ornamental borders. They can also be grown as companion plants in the vegetable garden and are eminently suited to growing in containers, hanging baskets and window boxes. They are especially useful if grown near the kitchen.

Herbs range from tall showy herbaceous plants such as fennel (*Foeniculum vulgare*) and tansy (*Tanacetum vulgare*) to ground-hugging cushion plants such as thyme (*Thymus vulgaris*). The majority of herbs originate from dry sunny environments and so need sunshine to help them develop their essential oils. It is best to site herbs in an open, sunny spot in the garden where they will thrive.

Left: *Herbs are an important element in both ornamental and kitchen gardens, being decorative as well as useful.*

## SOIL PREPARATION

Drier sites suit most herbs, and the sunnier and hotter the site the better they will taste. The taste and smell of herbs is usually due to the production of essential oils within the plants. If they are grown in hot conditions, then the concentrations of essential oils will be greater. Growing herbs in very moist rich soils can accelerate their growth, but will result in a milder flavour. They will also look better and flower less than their "hot-site" counterparts and be easier to harvest.

Herbs are, however, best grown in a soil that is loamy with some added organic matter. The ideal pH is 6.5 to 7.0, which means that herbs can easily be planted among vegetables in the kitchen garden.

## SOWING HERB SEED

Herbs may be sown directly in the soil outdoors, just like vegetables. The preparation of the seedbed and the sowing techniques are exactly the same, and they can easily be interplanted or block planted among other vegetables.

Alternatively, herb seeds may be planted under cover, raising them in the same way as early vegetables and bedding plants and then hardening them off before planting out in the garden. This method is especially useful for more tender, leafy herbs such as basil or coriander (cilantro).

Above: *You can restrict the spread of invasive plants such as mint (*Mentha*) by planting them in pots or buckets that are then buried in the ground.*

Above: *Pinching out newly planted herbs such as this bay (*Laurus*) will encourage bushy, leafy growth.*

Basil (*Ocimum basilicum*), for example, associates well with outdoor tomatoes, both in the garden and in the kitchen. These can be planted out together from an indoor sowing and the crop will be mutually complementary. Indoor sowing can also provide you with herbs that can be cropped earlier in the season, effectively extending the useful life of your organic herb garden.

## PLANTING HERBS

**1** *Excavate a planting hole that is about a quarter to half as big again as the plant's rootball. Make sure it is deep enough.*

**2** *Ensure that the top of the compost is the same level as the surrounding soil. Refill the gap around the rootball and firm the soil.*

**3** *Water the plant immediately after planting. Keep the plant well watered until it is fully established into the surrounding soil.*

### PLANTING HERBS IN THE GARDEN

Herbs can be sited anywhere in the garden as long as it is sunny. They have a range of forms and colours and often make valuable additions to the ornamental garden. Foxgloves (*Digitalis*), sage (*Salvia officinalis*) and the curry plant (*Helichrysum italicum*) are a few examples of herbs that can be used in annual and herbaceous borders as well as in the kitchen garden. Some herbs, such as mint (*Mentha*) and lemon balm (*Melissa officinalis*), can become very invasive if they are not contained in a pot or sunken sink when growing among other plants in an ornamental border. Remove the flower-heads from the mint before they have had a chance to seed, as the seed will germinate all over your border.

### PLANTING HERBS IN CONTAINERS

Herbs make excellent subjects for use in pots and containers and are wonderful for patio gardens that catch plenty of summer sun, although you need to make sure that the potting mix never dries out. Raised beds, which provide good drainage, are also good areas for growing herbs. Always plant them in a free-draining potting mix that will not become waterlogged. There are numerous cultivars of culinary herbs that can be used for ornamental purposes, and groups of pot-grown herbs can be extremely decorative as well as supplying you with a range of fresh flavourings. Thyme, rosemary, lavender and sage are all good choices to grow in pots, either outdoors or on your windowsill.

Above: *Herbs are easily grown in a container which will provide an excellent focal point in the kitchen garden.*

Herb pots require little maintenance, save for watering and the occasional feed during the growing season. Most are rarely long term and are best restarted yearly or every other year. Herbs that are permanently in pots, such as bay trees, will need repotting every year. Spreading subjects like thyme can be lifted and both top-pruned and root-pruned prior to repotting.

Mint and other spreading herbaceous subjects may need dividing and repotting from time to time. This is done by splitting the crown of the plant into smaller pieces and then repotting one of these back into the container with some fresh potting mix. Dividing in this way is best performed annually for very vigorous herbs. Harvesting on a regular basis is often enough to control the growth of many potted herb arrangements (where a number are planted in one container), but a light trim may also be necessary from time to time.

Potted herbs may also be grown in the greenhouse to ensure a supply both earlier and later in the season. Try growing basil (*Ocimum basilicum*), coriander (cilantro; *Coriandrum sativum*), chives (*Allium schoenoprasum*) and dill (*Anethum graveolens*) in pots because this will save money if you spend a lot on fresh herbs. Pots raised under glass can be brought into the kitchen for ease of use. A series of successional sowings under glass will ensure that you have fresh herbs for most or even all of the year, both indoors and out.

Above: *Planting spreading herbs such as thyme (*Thymus*) in pots will help to control them and can also be decorative.*

# HARVESTING AND STORING HERBS

*Many commonly used culinary herbs such as basil, coriander (cilantro), chives and parsley can be grown indoors on a windowsill or conservatory during the cooler winter months if you have space. If you are not able to spare growing room for these, most are easily stored for use later. Herbs are easily harvested and most of the storage techniques are simple and straightforward.*

Above: *Aromatic herbs such as rosemary (*Rosmarinus officinalis*) can be used to flavour bottles of olive oil.*

## HOW TO HARVEST HERBS

Various parts of herbs, including the leaves, flowers, fruits and seeds, are gathered at different times, depending upon the plant and the part that provides the desirable properties. Annual leafy herbs such as basil (*Ocimum basilicum*) and parsley (*Petroselinum crispum*) should be carefully picked, never taking more than about 10 per cent of the growth in a single picking.

The same is true of perennials such as sage (*Salvia officinalis*), thyme (*Thymus vulgaris*) and rosemary (*Rosmarinus officinalis*) because severe pruning or over-stripping of the leaves will weaken the plant. It is important that you not remove more than one-third of the growth at any one time. If you harvest carefully, you will get a more vigorous leaf growth that will result in healthier plants.

Above: *The best time to harvest herbs is usually just before they flower. This is when they have their strongest flavour.*

As a general rule, pick herbs just before the plant is about to flower, which is when they have the strongest flavour. Pick the leaves when they are fresh and at their sweetest, selecting blemish-free, upper leaves. Collect the leaves in early morning or late evening, provided they are dry, rather than in bright afternoon sun when the plant's sap is rising. This is when the aroma of herbs is at its strongest and is easily lost if picked during this time of day. Flowers such as borage (*Borago officinalis*) and lavender (*Lavandula*), however, are best picked just before they reach full bloom and once they begin to open in the heat of the day.

Rhizomes, like ginger and turmeric, are collected in autumn, just as the leaves begin to change colour and the maximum amount of nutrition has been stored. Use a fork to gently free the roots from the soil and always avoid "hand-pulling" them. Choose only the best ones and use a vegetable brush to gently loosen any dirt. If you do need to wash them, do so quickly in cold water and avoid soaking them, as this can result in lost flavour.

Harvesting seeds tends to vary from plant to plant. Some seeds, like those of borage, simply fall to the ground as soon as they are ripe. Thyme seeds are very small and hard to see. Parsley and coriander seeds shake off very easily, and frequently the plants will have sown next year's crop for you before you realize they have gone to seed. One method of harvesting any seed that is difficult to collect is to tie a small paper bag over the flower head when the seeds start to form, ensuring that you can collect the seed without losing any. It would be advisable to use this method for collecting from plants with small seed as they can drop off when ripe or sometimes spring from the plant.

Above: *Herbs can be dried for later use by hanging them in bunches in a dry place out of direct sunlight.*

## DRYING HERBS AND FLOWERS

Store herbs in a cool, dry place with minimum exposure to air and sunlight. One of the most popular methods of preserving them for use during the winter months is drying. This method can actually improve the flavour of some herbs, particularly the leaves of bay trees (*Laurus nobilis*). Herbs may be dried in bundles secured with a rubber band or string and hung upside down from a rack in a dry location such as an airing cupboard or shed.

When drying the herbs, the temperature of the area should not exceed 30°C (86°F) because the plants' essential oils will evaporate at or above this temperature. Do not dry your herbs in the kitchen where they will be spoiled by the humidity caused by cooking.

Fresh herbs can also be placed in brown paper bags. Remember to label the bags because it will be hard to distinguish between the herbs once they have dried. Store in a dry, dark, cool place until the herbs inside are dry, shaking the bags occasionally so that the plants dry evenly. Remove any stems and store the dried herbs in airtight jars. Keep the jars away from light to protect the colour and flavour of the herbs. Roots are best chopped into small pieces and dried in an oven. In general, you can expect those that you have grown and dried yourself to last at least two years.

## STORING HERBS

Herbs can also be preserved in other ways, so that you can use them in cooking throughout the year.

**Herb salts** In a cool oven, spread a layer of ground salt on a sheet of greaseproof (waxed) paper. Sprinkle the chopped fresh herbs on top of the salt and bake for 10–20 minutes. When the herbs are dry, let them cool and place in a jar. Chives, oregano, thyme, lemon balm, lemon thyme, parsley, rosemary and basil can all be treated this way.

**Puréeing** This method involves mixing approximately 60ml (4tbsp) of olive oil with 2l (8 cups) fresh basil leaves which have been washed and dried. These are blended in a processor until puréed before being transferred to a jar. Stir each time you use it and top with a thin layer of oil afterwards. The purée should keep for up to one year in a refrigerator.

Above: *After herbs have been hung up to dry, separate the seeds from the dry flower heads before storing in tightly sealed jars.*

**Freezing herbs** Herbs such as dill, fennel, basil and parsley freeze well. The herbs should be cleaned and put into separate, labelled freezer bags. Alternatively, chop the leaves and freeze them with a little water in ice-cube trays. Chop the herbs finely, filling each cube, half with herbs and half with water, before freezing. Transfer the frozen cubes to plastic bags and label. Frozen herbs are best used within six months.

## HERBAL INFUSIONS

You can also make a hot infusion of leafy herbs by placing the herb and any fine-quality olive oil in a glass bowl. This is then placed over a pan of gently simmering water and heated gently for about three hours, ensuring that the water in the pan does not dry out. The strained oil, once it has cooled, should be stored in airtight bottles or jars.

A cool infusion of flowery herbs involves using fresh herbs such as chamomile which are ground with a pestle and mortar and packed into a large jar and covered with oil. The sealed jar is then left in a warm, sunny place for two to three weeks and shaken occasionally. It is then strained and placed into airtight jars or bottles where it can be stored for up to a year.

A simple way of creating aromatic olive oil is to simply add a large sprig of your chosen herbs – rosemary and mint are good choices – to a bottle of olive oil. Store the bottle in a cool dark place for about ten days before using.

You can also make you own herbal vinegars by adding fresh herbs such as tarragon or rosemary or cloves of garlic, slices of ginger, chillies or peppercorns and all-spice powder to white vinegar. Crush about a quarter litre volume (1 cup) of loosely packed fresh herbs for each litre of vinegar. If you are using dried herbs, use half the amount of herb stated above. It is important that you use only commercially prepared vinegars, as homemade vinegar may not have a low enough pH to prevent bacterial growth. Place the vinegar in a pot on the stove and heat, but do not boil. Place the herbs in a clean, sterilized jar and slightly crush them. Pour the vinegar over the herbs and cover the jar tightly. Let the herb-vinegar mixture steep in a dark place at room temperature, shaking the jar every couple of days. After a week, strain the vinegar and place in bottles and store for up to six weeks.

## DRYING AND FREEZING HERBS

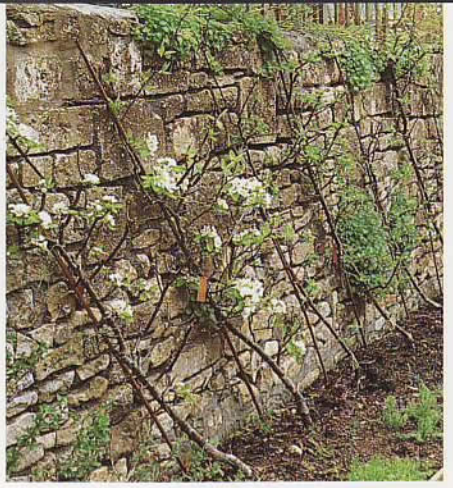
**1** *Pick seed just as it is ripening. Place the seeds on a tray or in a paper or muslin bag. Leave in a cool, dark place for a few days until the seed is completely dry.*

**2** *Herb seeds that have been dried can be stored in old glass jars with an airtight lid. Store the jars in a cool, dry, dark place and label them for future reference.*

**3** *Herbs can be frozen in ice-cube trays. Fill the trays with water after you have added the herbs to make ready-to-use cubes. Herbs can also be packed into freezer bags.*

# GROWING FRUIT TREES AND BUSHES

*Freshly picked fruit from the organic garden tastes absolutely delicious. The warm taste of a juicy sweet raspberry or the crisp flavour of a tree-ripened apple would tempt many a gardener into growing their own fruit produce. The tastes can be quite different from shop-grown produce where storage, handling, packing and off-the-tree ripening all take their toll on the quality and taste of the fruit.*



Above: *A sunny wall provides an ideal location for growing fruit trees, such as this pear, that need warmth.*

## WHERE CAN FRUIT BE GROWN?

Fruit trees and bushes can be grown wherever there is space. Strawberries can be used in hanging baskets or tubs, dwarf apple trees can be planted in ornamental containers and a number of fruits, such as cherries, white and red currants and figs, can all be grown against walls. Fruits not only provide produce for the kitchen table but many of them have ornamental qualities and can blend well with other plants in the decorative garden.

## CHOOSING A SITE

The best site for fruit, both indoors and out, is a sunny one. Sunlight is essential, not just for the ripening of the fruit itself but also for flower bud formation and flowering. In addition, fruit trees and bushes often appreciate a sheltered spot where even exotic fruit can be raised. Within the garden a sheltered sunny wall can provide the ideal place to grow peaches, apricots or figs. If cold winters are a problem, then provide winter protection in the form of a portable frame or, alternatively, grow the plants in a greenhouse. It is worth noting that providing your plants with the ideal conditions for healthy growth will reap its rewards in the end. Not only will you harvest heavier yields, but, more importantly, your plants will be less prone to pest and disease attacks, which is an obvious advantage when growing organically.

Left: *Most fruit bushes will benefit from a generous application of well-rotted manure or compost early in the year.*

## SELECTING THE RIGHT PLANTS

Variety selection should not be based purely on hardiness but on personal preference. You may also wish to consider how easy the fruit tree or bush is to grow, fruit size, taste and the time of harvest. Selecting more than one variety can result in having fresh fruit over a longer period due to a succession of ripening.

Some fruit trees combine the best qualities of two plants. Grafting utilizes the qualities of the variety as top growth (scion) and other desirable qualities from a rootstock that may be absent from the variety. The scion is the fruiting variety that is budded or grafted on to the rootstock which is selected for certain characteristics such as dwarfing, nematode insect resistance, soil type, cold hardiness and disease resistance.

The most commonly grown rootstocks for amateur gardeners are the apple semi-dwarfs and dwarfs. Grapes are also grafted on to clonal rootstocks, although they are often supplied on their own roots. Figs, olives and various types of berry are also usually supplied as plants on their own roots.

Dwarf apple trees are very useful in small gardens and are eminently suited to container growing. They produce fruit of the same size, colour and quality as larger standard trees and require the same pruning, nutritional and care regimes as a standard-size tree.

Dwarf trees fruit much sooner after planting and bear less fruit per tree. When harvesting the fruit, you can reach all parts of the tree from the ground without using a ladder and the trees are easier to train and prune on an annual basis. Grafting the desired variety on to special clonal rootstocks "dwarfs" apples. The most popular dwarfing rootstocks for apple were developed in England and are designated as either EM or M (for East Malling) or MM (for Malling Merton). Dwarfed trees must be pruned annually or size control may be lost. In addition, loss of fruit by frost or pests will also increase growth so necessitating summer pruning.

## PLANTING FRUIT TREES AND BUSHES

As with any other type of tree, good ground preparation and careful handling are essential steps to successfully establishing your fruit trees and bushes. The cheapest option when buying fruit trees is to purchase bare-rooted plants. The disadvantage is that they are only available during the dormant season. The most important factor in handling bare-rooted plants is not to let the roots dry out. When you buy trees always check the condition of the roots and packing material. Heel in plants by covering the roots with moist soil in a cool environment outdoors if they are not to be planted immediately.

Dig a hole slightly wider and deeper than the spread and length of the root system, making sure the sides of the hole are not "glazed" over as this will result in a root girdling. After trimming diseased, dead, broken or extra long roots, place the tree in the hole and spread out the roots. For larger trees, place the stake in the hole and drive it in (remembering to first remove the tree and cover the roots). Place the tree back into

## PLANTING A FRUIT TREE

**1** *Dig a hole in the ground that is at least half as large again as the rootball of the fruit tree. Loosen the sides and the base of the planting hole with a garden fork.*

**2** *Remove the pot and check the rootball for girdling roots. Tease these out by hand or with a garden fork.*

**3** *Use a straightedge to make sure that the plant is at the right depth in the hole. Fill around the roots with soil, firm it down and water well.*

**4** *Hammer in a stake at an angle of about 60° in order to avoid the rootball and place a tie on the tree. Saw off the end of the stake. Nail the tie to the stake to secure it.*

**5** *The tree should remain staked for approximately one year. As the diameter of the tree stem increases, loosen the tree tie as required.*

the hole and return the soil, firming in layers of about 30cm (12in) as you go. This avoids large air spaces being left around the roots and ensures that it is set firmly. Trees should be planted at the same depth as they were grown in the nursery. Make sure the bud union (for trees on rootstocks) is about 5–7cm (2–2¾in) above the soil line. Do not place fertilizer in the planting hole as this can be added later. Mulch the newly planted tree with well-rotted manure or compost to suppress weeds. Container-grown nursery stock can be transplanted any time of the year. Site preparation is the same as for bare-rooted stock. Make sure that you check the roots as they can become distorted or root bound if they are grown in containers for a long period of time. Teasing these roots out can help avoid root girdling, but the best way to do this is to use field-grown (bare-rooted) stock.

### PRUNING NEWLY PLANTED STOCK

Fruit trees must be pruned when they are planted for a number of reasons. If planting bare-rooted stock, the top of the tree must be pruned to counter-balance the loss of the root system which would have been severed in the nursery during lifting. Pruning also forces the growth of laterals from which the future framework of the fruit tree will be selected. Branches that are desirably located can be retained as part of the framework whereas undesirable branches are removed.

### FRUIT TREE POLLINATION

Pollination is the transfer of pollen from the male part of the flower to the female part of the flower (the stigma) to allow fruit to set and seeds to develop. Seeds cause the fruit to develop properly.
If both the pollen and stigma are from the same flower or from another flower from the same variety, the process is called self-pollination. Fruit trees that set fruit as the result of self-pollination are called self-fruitful, whereas those relying on pollen from a different variety are called self-unfruitful. The latter needs two varieties near to each other for fruit set to occur. This is called cross-pollination.

**Apples** Apples generally need two varieties for good fruit set. This can be another apple variety or a crab apple that blooms with the edible crop.
**Apricots** Self-fruitful
**Berries (all types)** Self-fruitful
**Cherries** Sweet cherry is self-unfruitful and needs two varieties for good crop set. Sour cherry varieties are self-fruitful.
**European plums** Self-fruitful
**Figs** Self-fruitful
**Japanese plums** Self-unfruitful as a rule with the exception of Santa Rosa which will set fruit fairly well without cross-pollination.
**Nectarines** Self-fruitful
**Peaches** Self-fruitful with the exception of 'J.H. Hale' which has to be pollinated by another variety.
**Pears** These always need two varieties to ensure good fruit set.

# SUPPORTING FRUIT TREES AND SHRUBS

*Many of the fruits that we grow, such as free-standing apple or plum trees, require support only in the early stages, whereas other fruits, like the raspberry, need this throughout their lives. Supports benefit the plants in a number of different ways. They help in establishing strong roots and can prop up trained specimens such as cordons and espaliers. This helps to maintain healthy vigorous growth and increase fruit yields.*

Above: *Apples can easily be grown in rows as cordons that are supported by a framework of stakes and wires.*

## WALL AND FENCE FRUIT

The training of fruit on a wall or a fence is carried out to gain the maximum production of high-quality fruit in a limited space. As well as being ideal for a small garden, this can also look extremely decorative. Numerous training systems, based on the art of espalier which originated in France and Italy about 400 years ago, have been devised. The most useful training systems used in gardens today are the fan, espalier and cordon. Apples, pears and plums are all suited to this method of training, which is usually supported by a wall, fence or wire trellis. The plants are normally held to the wall or fence using wires which are held in place by vine eyes, positioned 60–90cm (2–3ft) apart. The wire is led through the holes in the vine eyes and secured at both ends. The wires should be no more than 30–45cm (12–18in) apart.

## FREESTANDING WIREWORK

Raspberries, blackberries and other hybrid berries are all grown on a permanent framework. They are usually grown on a freestanding structure that supports the loose growth of the plants. To build such a structure, insert a post at least 60cm (24in) into the ground at the end of each row. Brace each end post with another post set at a 45-degree angle. Insert intermediate posts between the two end ones at a distance of every 2m (6½ft). They are set in at the same depth as the end posts, but no bracing posts are needed. Fix the wires on to the posts so that they run the length of the support. Place the first wire 60cm (24in) from the ground, pull tight and attach to the posts using staples or eye-bolts. The other wires are attached at 30cm (12in) intervals until they reach the top of the support. The final height depends on the height of the fruit.

## INDIVIDUAL SUPPORT

When they are first planted, all free-standing trees require support to help them to establish a strong healthy root system. You can use a stake to support a fruit tree, ensuring that the stake is placed on the windward side of the tree. The stake is inserted before the tree is planted and is driven well into the ground. The general rule is to have a stake that is one-third the height of the tree showing above the ground. The tree is then tied to the stake using a tree tie. Do not use string or rope because this can damage the bark. A low stake such as this will allow the top part of the tree to move about freely and so help the tree to thicken and strengthen its trunk. For most fruit trees the stake should only be left in the ground for approximately one year and not for several years as is commonly practised.

## STAKING A FRUIT BUSH

**1** *Using a large mallet, drive a strong wooden post into the ground at the end of a row of the fruit bushes to a depth of about 60cm (2ft).*

**2** *Fix another strainer post at a 45-degree angle in order to support the upright. Place this on the side the wire is to run and nail it firmly.*

**3** *Fix the wires to one of the posts and then stretch these tightly along the row, stapling them at each post along the row as you go.*

**4** *The fruit bushes can be fastened to or trained along these wires. Take care not to tie stems too tightly as this will damage them.*

# PROTECTING FRUIT

*There can be few more frustrating events in the kitchen-garden calendar than losing your fruit crop (or a fair portion of it) to birds. However, we have to remember that birds are a strong ally in the fight against pests in an organic garden and should be encouraged into fruit-growing areas when the bushes are not fruiting. Protection for the fruit crops will therefore need to take the form of moveable cloches or fruit cages where the netting can be removed after fruiting has taken place.*

Above: *Cloches can be used to protect young strawberries from bad weather and also to keep pests at bay.*

## FRUIT CAGES

This is perhaps the easiest way to protect tall fruit crops such as blackcurrants, raspberries and gooseberries because these plants can all be grown under the one structure. This makes it easy to maintain and harvest the fruit.

A permanent fruit-cage structure with removable netting is the ideal scenario because the netting can be put in place just before the crop ripens and then is taken down again after fruiting has occurred. This allows the birds to roam freely around the area at all other times, but without jeopardizing the crop at fruiting time. Alternatively, a series of small cages can be constructed over crops that ripen at different times, netting each of them individually as the fruit begins to ripen. This is a wildlife-friendly way of protecting the fruit, but it is also time-consuming.

Above: *A tunnel of wire netting is ideal for protecting ripening strawberries from pests such as birds.*

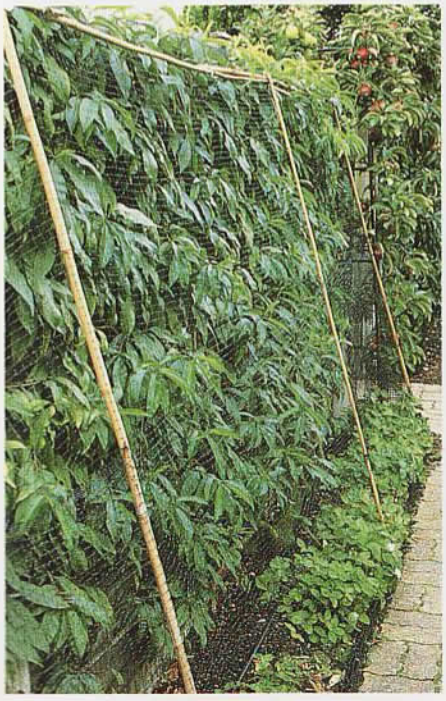
## LOW-LEVEL PROTECTION

Smaller- or lower-growing crops, such as strawberries, can also benefit from a barrier to protect them from birds. This is easily achieved, as the structure does not need to be large, permanent or even particularly sturdy. One simple method is to form a low tunnel of chicken wire, supported on hoops that are bent into an inverted U-shape. For larger areas, a series of stakes hammered into the ground can be covered with netting to keep the birds at bay. Plants growing on wire trellises can be protected with netting draped over the stakes and top wires and weighted at the base with stones.

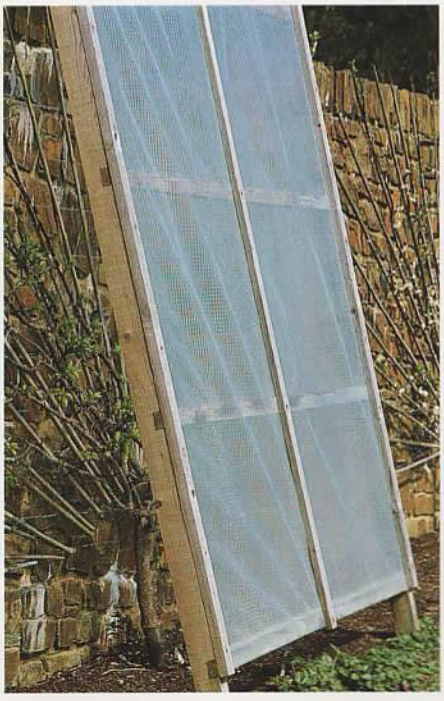
Larger bush fruit can be covered with netting and weighted down with stones. A little of the crop may be accessible to birds, but most will be protected.

## PROTECTION WITHOUT BARRIERS

Most bird deterrents depend upon shocking the birds or mimicking something that they are naturally afraid of. Scarecrows are an age-old favourite. Other deterrents mimic the shape of hawks or make noises that will startle the birds. A relatively recent "innovation" has been to hang compact discs from wires stretched through the crop. Most of these deterrents tend to work very well at first until the birds get used to them. However, the only drawback is that when the birds get used to them, they resume their onslaught with a vengeance. The only way to overcome this is to keep changing the deterrents every few days.



Left: *Fruit trees growing against a wall can easily be protected with a cost-effective frame that is covered with netting.*



Right: *Fleece stretched over a frame can help protect the blossom of wall specimens from late frosts.*

# PRUNING FRUIT TREES AND SHRUBS

*The general purpose of pruning fruit trees is to regulate growth, increase crop yields and to improve fruit size and quality. The fruit trees also need to have all the dead, diseased and damaged wood removed as well as overcrowded areas thinned out. Pruning is also performed in order to establish a tree with a strong framework that is capable of supporting heavy crops without causing damage to the plant.*

Above: *The careful pruning of trained specimens, such as this pear, will result in good blossom and improve fruit yields.*

## WHEN TO PRUNE FRUIT TREES

If a fruit tree is pruned in spring, all the effort that the tree has put into bud production is wasted. The best time to prune is in winter when the plants are dormant and the sap has not yet started to rise. This applies to all fruit except for plums and cherries which are susceptible to silverleaf disease at this time and are best pruned in summer.

Summer pruning is also recommended if you wish to control vigorous growth in formally trained fruits such as fans, cordons and espaliers.

When pruning is underway, older fruit-bearing trees should be pruned first. Young, non-bearing apple trees and stone fruits can be pruned later to minimize the risk of winter injury.

## BASIC PRUNING CUTS

Although there are different methods of pruning and training, the pruning cuts are the same. Always make the pruning cut just above a bud, ensuring that the cut is angled away from the bud. This will allow rainwater to drip down the other side of the stem and away from the bud, thus protecting the top of the cut from rotting.

Larger branches will need to be cut with a saw. If the branch is very heavy, you will need to remove the branch in three separate stages. Cut underneath the branch first, 20–25cm (8–10in) away from where the final cut will be. Make the second cut on the top of the branch just behind the first undercut. Follow this through until the weight of the branch makes the wood split and it falls off cleanly at the undercut. You will then need to make a third cut at the branch collar, cutting straight from the top to the bottom of the branch as there is no weight left to tear the bark.

### BENEFITS OF PRUNING

Pruning fruit trees and bushes has many advantages, some of which are outlined below.

- Increased fruit yields.
- Can aid ripening of the fruit.
- Maintains healthy growth.
- Regulates growth.
- Improves fruit size and quality.
- Controls the spread of diseases.

Above: *Training can give rise to a variety of ornamental shapes. These pear trees have been trained into a cylindrical shape.*

## PRUNING LARGE BRANCHES

**1** *Make a cut about 20–25cm (8–10in) out from where the final cut will be on the underside of the branch. Cut about a third of the way into the branch.*

**2** *Make a cut about 10cm (4in) nearer the position of the final cut, cutting until the branch snaps. The initial undercut prevents the wood splitting or bark from stripping.*

**3** *Position the saw for the last cut to avoid damaging the swollen area at the base of the branch. The cut will heal in a couple of seasons. No wound painting is necessary.*

### SUCCESSFUL FRUIT TREE AND SHRUB PRUNING

Pruning fruit trees is a very complex subject and, like so many areas of organic gardening, is the subject of opinion and hot debate. Despite this it is possible to apply certain guiding principles that can enable you to prune your fruit trees and bushes successfully.

1 **Remove root suckers arising at the base of the tree**
These compete with the upper growth for water and essential nutrients and their dense habit can harbour pests.

2 **Always cut out dead, dying, damaged or diseased limbs first**
Helps to maintain the plant's health and enables you to see precisely what needs doing next.

3 **Remove low, drooping limbs**
These will not bear fruit and will often be heavily shaded by growth above. They are an unproductive drain on the tree.

4 **Remove upright growth or outward growth in the case of wall-trained bushes**
Upright growth will produce a flush of growth at the end and will not fruit well. Branches growing away from the wall will shade the fruit behind causing poor ripening.

5 **Remove crossing or dense parallel growth**
Crossing growth will rub and can cause bark damage that will allow disease entry. Dense growth will also shade the developing fruits. This will slow and limit the ripening of the fruit.

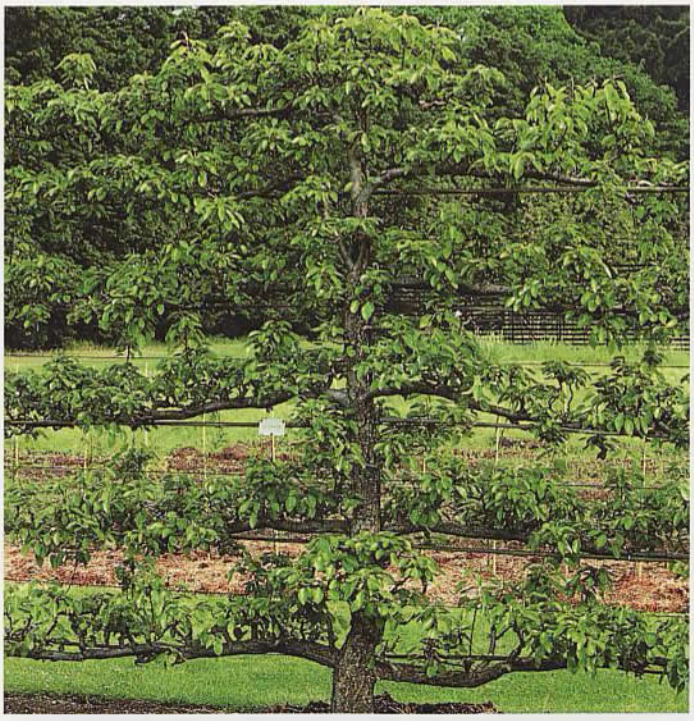
6 **Freestanding trees should have upper limbs cut back further than lower limbs**
This will result in the development of a conical shape that will allow light penetration all the way down the side. Fruit will ripen more evenly.

7 **Remove water sprouts as they develop**
Water sprouts can quickly develop and cover the developing fruits, causing poor ripening and harvesting difficulties. They can be easily removed by hand. This is best done early in the season when the growth is soft and is therefore easily removed. Carry out regular inspections throughout the season to control the water sprouts.

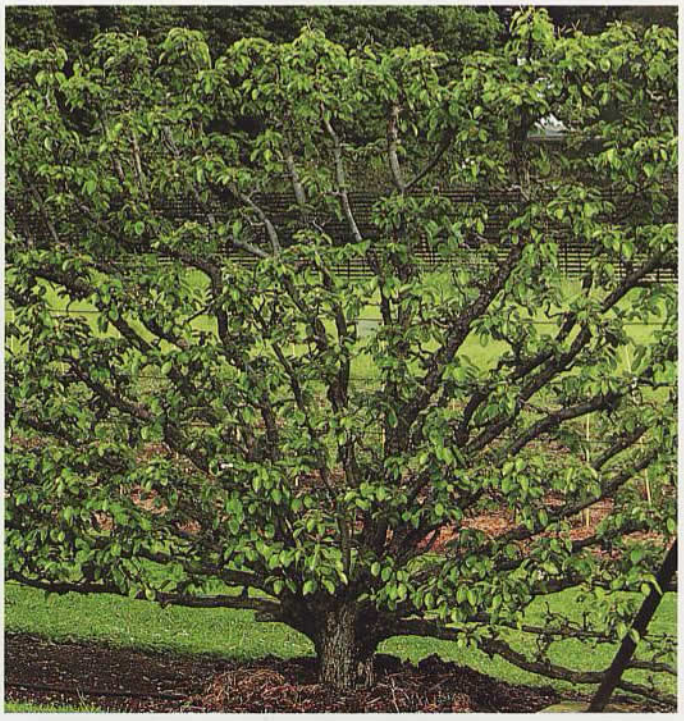
8 **Once the larger cuts have been made, thin out the smaller branches**
Removing thick branches first allows you to see what remains to be done and also makes it easier to get to the remaining pruning work. Removing older wood encourages young growth to fill the gap. Remember to stand back and view what you have pruned as you go along.

9 **Always make clean cuts above a leaf bud or close to the stem**
Pruning cuts that are not performed cleanly or that leave a long stub will damage the plant tissue and encourage the entry of pests and diseases.

10 **Avoid feeding with nitrogen for a season before and following heavy pruning**
Both pruning and high nitrogen fertilizers promote the development of rapid growth flushes that can result in the poor development of the crop.



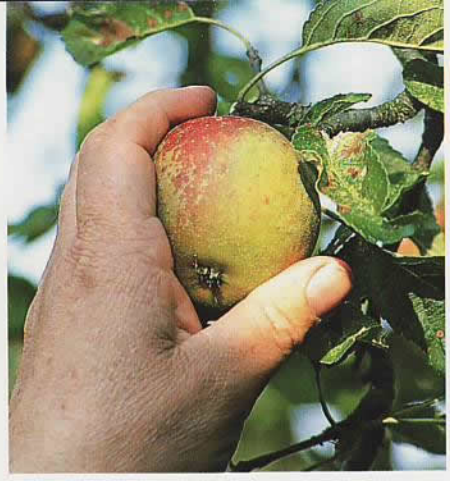
Above: *This well-established pear tree has been trained into an espalier on wire supports. Many fruit trees can be grown and supported in this way.*



Above: *This pear tree has been grown as a fan. Fans are an ideal way to train many species of fruit tree and are well suited for growing against a wall.*

# HARVESTING AND STORING FRUIT

*When harvesting your fruits, you will find that there is only so much you can eat fresh or give away. There is always surplus fruit left over and you are faced with the question of what to do with it. Leaving some on the plant to help feed the wildlife in your organic garden is a good idea, but storing the rest of the excess fruit using a variety of methods will ensure that you can eat your home-grown produce over a longer period of time.*



Above: *An apple is ready to be picked if it can be removed from the tree with only a single twist of the fruit.*

## HARVESTING

The key to successfully storing fruit begins well before harvesting commences. Your first objective should be to grow fruit that is as healthy as possible because it will be the best for storage. Harvesting immature crops or attempting to save those that are in poor condition – due perhaps to a lack of water or nutrients or to pest and disease damage – can lead to many storage losses.

There are several ways that fruit can be stored and the condition of the picked crop will usually be the deciding factor as to which of these you should use. Top fruit such as apples and pears can often be stored fresh through most of the winter, whereas stone fruits and berries, such as peaches, strawberries and raspberries, must be quickly consumed, turned into a preserve or frozen.

Careful handling, both during and following harvesting, is essential because, from the moment they are harvested (and in many cases well before), crops have no means of repairing any physical damage that they may suffer. Even firm, strong-looking fruit such as apples can easily be bruised, although the damage may well not show up immediately.

As well as good handling, a careful selection of the fruits during harvesting is essential for successful storage. You should inspect the picked fruits and select only those of the best quality for fresh storage. Reject any that have a broken skin or show any sign of pest or disease damage. Do not throw them on the compost heap yet, however, because damaged fruit may well be useful for making preserves such as jellies and jams or for freezing.

It is also a good idea to leave a small percentage of mature fruit on the plants when you are harvesting to help feed the wildlife in your organic garden.

## STORING

In general, the storage area for fruit must be frost-free, safe from pests, rainproof and ideally kept at a constant temperature.

### STORING FRUIT

To store surplus fruit and avoid the risk of rotting, make sure that you use the appropriate method.

**Apples, pears and quinces**
Store in a cool place for up to 12 months, depending on the variety.
**All other fruit** Eat immediately or freeze. Alternatively, preserve fruit by bottling or making into jam. Fruit can be kept for up to 12 months, depending on the method of preservation that has been used.

The long-term storage of any fruit calls for cool conditions with adequate ventilation. If you have space, consider having a separate refrigerator specifically for fruit storage, or choose an area with a low temperature that does not go below freezing. A garden shed or garage can be ideal, in many cases, but even these

Far left: *Pick soft fruits, such as strawberries, raspberries and gooseberries, carefully to avoid bruising the fruit.*

Left: *Pears can last for up to 12 months, depending upon the variety. Lay them in a recycled box, ensuring that the fruits do not touch and air can circulate around the fruit.*

Above: *Fruit trays, recycled from supermarkets, make ideal storage boxes for surplus fruit. The trays should be kept in a cool dry place such as a garage or shed.*

Above: *Soft fruit is best placed in small individual containers as it is picked to prevent it being squashed and spoiling. Store in a refrigerator or other cool place.*

spaces may need extra insulation if winter weather conditions become severe. Some houses have a basement, cellar or unheated room that may be ideally suited for the task. Attics are not recommended for fruit storage because of their wide temperature fluctuations and variable humidity.

It is worthwhile trying out a variety of different storage methods. This can be done by splitting the crop up and then trying out different locations in your home. You will soon find which are the best places to store fruit, and what areas are best for storing a particular kind of fruit.

Ensure that you check the stored fruit regularly, at least weekly, removing any that show signs of decay. Remember the old adage that "one bad apple spoils the whole barrel"? This can be true for your crop too unless you prevent rots from spreading. The unblemished parts can often still be used for eating or cooking. If lots of fruits begin to rot simultaneously, it could be that the storage conditions are not suitable, the crop has reached its maximum "shelf-life" or the fruit was not of sufficiently good quality to start with.

## FREEZING AND PRESERVING

Freezing is an excellent way of storing all the surplus fruit that has been produced in your garden. Unfortunately, fruit tends to lose its firmness once it has been frozen, although the taste will remain more or less the same. Raspberries, for example, are best used for making pies or flans after they have been frozen and will be of very poor quality if they are eaten raw. Most fruits can be frozen after they have been stewed or puréed; this is true of fruits such as apples and plums.

Fruits like strawberries and blackcurrants that are not suited to long-term storage can be made into jams, pickles and chutneys. You can find recipes for these in good cookbooks.

Above: *One of the simplest ways of preserving fruit is to freeze it, although once frozen most fruits are only good for cooking.*

Above: *Adding a favourite fruit such as these cranberries to good wine vinegar can produce interesting flavours.*

Right: *Bottling fruit in alcohol is an ideal way to preserve soft fruits such as peaches, nectarines and apricots.*

# CALENDAR OF CARE

## WINTER

### THE ORNAMENTAL GARDEN

**EARLY WINTER**
- Continue cultivating the soil, if not already done, when the ground is not wet.
- Continue planting and transplanting on mild days.
- Press plants that have been lifted by frost back into the ground.
- Plant herbaceous perennials for next year.
- Last chance to plant roses.
- Move greenhouse plants to the house as they come into flower.
- Start pruning deciduous shrubs and trees during spells of fine, frost-free weather.

**MID-WINTER**
- Finish digging and trenching and fork over borders.
- Order seeds for coming season.
- Protect autumn sown annuals from frost.
- Prepare ground that is to be planted out with bedding plants with manure.
- Tidy up climbing plants and remove any dead wood.
- Firm down herbaceous plants that have been lifted by the frost and protect the new shoots of young tender plants.
- Plant evergreen and deciduous shrubs.
- Trim deciduous hedges and shrubs to start bringing them into shape.
- Take hardwood cuttings and layers of deciduous shrubs.
- Sow annuals in gentle heat.
- Take cuttings of tender shrubs and start under gentle heat.

**LATE WINTER**
- Tidy up unused ground and apply a top-dressing of manure or leaf mould.
- Protect bulbs from mice, snails and birds.
- Prune roses planted this month.
- Start to train and trim climbers.
- Divide herbaceous plants.
- Sow annuals in gentle heat.
- Transplant autumn sown annuals.
- Plant edgings such as box (*Buxus*) hedging, pinks (*Dianthus*) or thrift (*Armeria*).

### THE WILDLIFE GARDEN

**EARLY WINTER**
- Try to maintain a fresh supply of clean unfrozen water for wildlife.
- To keep some open water on ponds, put in a floating ball or anchored block of polystyrene, preferably painted black, to absorb the warmth of the sun.
- Leave tidying the garden until late winter to shelter overwintering insects.
- Leave log and leaf piles completely undisturbed until spring.
- Feed resident birds with high energy supplements such as fat balls.
- Order seed now for early sowings of perennials and annuals.

**MID-WINTER**
- Put plenty of food in the garden for resident birds.
- Hang nesting boxes ready for breeding birds.
- Build dry-stone walls with gaps to provide shelter for reptiles and amphibians.
- Look out for wildlife tracks in snow and position cat deterrents at entry points.
- Provide food for non-hibernating mammals if present.
- Keep a record of wildlife to help you target future feeding and habitat creation.

**LATE WINTER**
- Continue feeding resident birds.
- Put up a range of different nesting boxes and make each box as inconspicuous as possible. Reposition any nesting boxes that were unused last year.
- Stretch wires or heavy-duty cord at least 10cm (4in) proud of walls and fences and train climbing plants to form a screen with a gap behind it for nesting birds.
- Trim one side of hedges to encourage dense new growth as nesting cover, but leave some flowering stems on spring-blossoming species such as hawthorn (*Crataegus*) for nectar.
- Protect bulbs from mice, snails and birds.

## SPRING

**EARLY SPRING**
- Feed lawns where the grass is thin and seed areas where the grass has been completely worn away.
- Prepare borders ready for biennials and perennials next month.
- Remove leaves and other debris from borders and fork over.
- Tidy up spring bedding plants.
- Sow hardy annuals when the weather is dry and mild.
- Start pruning roses.
- Trim box edging and damaged evergreens.
- Prick out annuals started last month.
- Start to harden off early seedlings ready for bedding out.
- Look for pests and diseases and deal with them as they occur.

**MID-SPRING**
- Hoe off weeds.
- Watch for signs of frost and protect young shoots.
- Watch out for pests and diseases.
- Give the lawn its first cut and tidy its edges.
- Stake and tie any plants that need it.
- Sow hardy annuals.
- Propagate hardy perennials, including water plants.
- Finish winter pruning and prune late winter/early spring flowering shrubs before they commence growth.
- Continue hardening off summer bedding and pinch out the tops.
- Trim and tidy up all climbers before they start into growth.
- Sow half-hardy annuals and take cuttings.
- Give box hedges their first clipping.

**LATE SPRING**
- Hoe off weeds.
- Finish off digging and rotavating to prepare the beds for planting.
- Water newly planted plants in dry weather.
- Keep an eye open for pests and diseases.
- Tidy bulb beds after the foliage has died down.
- Tie in sweet peas (*Lathyrus odoratus*) and check the support of other climbers.
- Finish sowing hardy annuals and plant out those raised under glass. Thin outdoor sowings and transplant where necessary.
- Plant half-hardy bedding plants when the danger of frost is over.
- Divide spring-flowering plants, like primroses (*Primula vulgaris*), for next season.
- Shrubs should have old wood removed and thinned out.
- Continue taking cuttings.

**EARLY SPRING**
- Put plenty of food in the garden for resident birds.
- Create a wildlife pond ready to plant up next month.
- Supplement the diet of resident early nesting birds with mealworms and waxworms.
- Emerging hedgehogs will benefit from a feed of cat food near their nesting sites.
- Hang nesting boxes for solitary bees.

**MID-SPRING**
- Plant new garden ponds and replace dead plants in established ponds.
- Sow seeds of hardy annuals in a sunny spot to attract insects during the summer until late autumn. Mix them up with salad crops to act as helpful companion plants.
- Install a "cage" of large-gauge chicken wire around nesting sites to allow nesting birds in but keep out magpies, grey squirrels and other nest-robbing species.
- Keep one or two nest boxes sealed so as to prevent the entry of resident birds until migrant bird species arrive.
- Continue feeding garden birds.
- Continue feeding hedgehogs until natural prey increases in numbers.
- Propagate hardy perennials, not forgetting water plants.

**LATE SPRING**
- Plant pot-grown seedlings of spring-flowering wild flowers in an area of lawn where you can leave the grass uncut until mid-summer.
- Sow the seeds of wild flowers thinly on the surface of gritty potting mix.
- Divide spring-flowering plants, such as primroses (*Primula vulgaris*) and cowslips (*P. veris*), for next season.
- Continue feeding garden birds.
- Put up bat boxes to encourage bats to roost in the summer.

# SUMMER

### EARLY SUMMER
- Mulch round plants and shrubs that need to be kept moist.
- Keep an eye out for pests, and keep weeds under control.
- Cut down and tidy perennials as they finish flowering.
- Feed roses and sweet peas (*Lathyrus odoratus*) with manure or compost tea.
- Sow biennials and perennials.
- Plant out plants raised under glass, dividing and planting out those that have finished flowering in other areas.
- Thin out seedlings and stake carnations (*Dianthus*), dahlias and sweet peas.
- Sow hardy annuals for autumn planting.
- Spray the foliage of new trees with water in hot or dry weather.
- Tidy up rhododendrons and other plants by removing seedheads, unless leaving them for decoration and food for the birds.

### MID-SUMMER
- Continue to hoe weeds and water newly planted specimens.
- Stake and tie plants.
- Layer or take cuttings from carnations.
- Pinch out the tops of chrysanthemums to prevent straggly plants.
- Water and feed sweet peas with a compost or manure tea.
- Sow perennial and biennial seeds for next year.
- Continue taking cuttings.
- Sow seeds for overwintering in the greenhouse.
- Pot plants that need repotting.
- Cut away dead and unwanted foliage on vigorous shrubs.
- Trim deciduous hedges.
- Propagate shrubs by cuttings or layering.

### LATE SUMMER
- Continue watering, mulching and hoeing.
- Remove all dead flowers, stalks and leaves.
- Train and tie clematis, honeysuckle (*Lonicera*) and wisteria.
- Trim plants such as lavender and penstemons after flowering.
- Water and feed sweet peas with a compost or manure tea.
- Take cuttings of old-fashioned roses.
- Thin perennial seedlings.
- Divide and replant spring-flowering perennials.
- Take cuttings of fuchsias, pelargoniums, heliotrope, hydrangeas and all half-hardy plants.
- Remove dead flowers and stalks from summer-flowering shrubs, unless they are berry producing.

# AUTUMN

### EARLY AUTUMN
- Hoe off any late weeds.
- Start tidying up for winter, but leave seedheads for birds.
- Put unwanted debris on the compost heap.
- Collect seeds and label for sowing next year.
- Start digging, manuring and rotavating heavy soils.
- Repair patches on lawns.
- Start collecting fallen leaves to make leaf mould.
- Tie and stake dahlias and tall shrubs.
- Cut back and support climbing plants.
- Sow spring-flowering seeds, starting with hardy annuals.
- Plant spring bulbs.
- Plant or transplant evergreen shrubs, conifers and herbaceous plants.

### MID-AUTUMN
- Collect fallen leaves to make leaf mould.
- Prepare areas for planting.
- Repair and lay new lawns, repair paths and walkways.
- Make final plantings of bulbs.
- Collect seeds of late-flowering plants.
- Lift and store half-hardy bulbs, corms and tubers.
- Lift, divide and replant herbaceous plants.
- Sow early sweet peas (*Lathyrus odoratus*).
- Start planting out spring bedding.
- If moving deciduous shrubs, do so to encourage new root growth.
- Take cuttings until the cold weather sets in.

### LATE AUTUMN
- Continue digging heavy and medium soils, leaving the light soils for spring.
- Spread surplus manure around flowerbeds if leaf mould is not available.
- Fork over herbaceous borders, leaving dead foliage until spring.
- Take cuttings of plants that may need replacing.
- Make final plantings of spring bedding.
- Take rose prunings from choice plants and push into the ground in a sheltered position where they may strike and give you more plants.
- Put bulbs for forcing under glass in pots.
- Plant flowering shrubs and trees for next season.

### EARLY SUMMER
- Plant tobacco plants (*Nicotiana*) to guarantee interesting night-flying moths and the bats that feed on them.
- Check fruit nets each day to ensure no birds are trapped inside.
- Choose bedding plants with simple flowers and keep a note of which the bees and butterflies prefer.
- Leave seedheads on spring-flowering shrubs such as rhododendrons as food for birds.
- Continue feeding garden birds, with seed and waxworms or mealworms, especially if there is a dry spell.

### MID-SUMMER
- Watch for night-flying moths on tobacco plants, late flowers on the honeysuckle, and tall yellow evening primroses.
- Continue to check fruit nets each day for birds.
- Take special care when turning compost heaps as grass snakes may be nesting and hedgehogs often sleep in them.
- Make log piles for wood feeding insects such as stag beetles.
- Lightly trim deciduous hedges if birds have finished nesting to encourage dense cover in the winter.
- Continue feeding garden birds, especially if there is a dry spell.

### LATE SUMMER
- Plant early spring bulbs now for nectar next year, especially for overwintering insects.
- Lightly trim nectar-rich plants such as lavender (*Lavandula*) and nepeta after flowering to encourage new growth.
- Dead-head herbaceous plants to encourage fresh flowers that give an extra boost to pollinators in the early autumn.
- Leave seedheads and berries on summer-flowering shrubs for birds.
- Continue feeding garden birds.

### EARLY AUTUMN
- Let one or two old vegetables flower, such as leeks, carrots and almost any member of the cabbage family, to boost nectar supplies for autumn insects.
- Look now to see if there is a shortage of nectar and redesign flower borders accordingly. Remember to select single-flowered plants where possible.
- Build new log piles, rock piles and brush piles ready for overwintering insects, reptiles, amphibians and mammals.
- Place nest boxes outside for overwintering mammals such as hedgehogs.
- Continue planting spring bulbs for early nectar next year.
- Plant evergreens to provide dense winter cover for birds and mammals.
- Continue feeding garden birds.

### MID-AUTUMN
- Start a new compost heap.
- Let hedge prunings, raspberry canes and other woody waste accumulate and leave them to become a hibernation heap for hedgehogs.
- Weed among and divide most pond plants before they die back. This removes excess nutrients from the pond and minimizes next summer's algal blooms.
- Pile weeds and thinnings from ponds at the side until the following day to give trapped pond dwellers time to escape.
- Place nest boxes outside for overwintering mammals such as hedgehogs.
- Continue planting spring bulbs for early nectar next year.
- Begin putting out high energy supplements such as fat balls for birds.

### LATE AUTUMN
- Plant hedgerows using native shrubs and trees.
- Plant late-flowering nectar plants like English ivy (*Hedera helix*) against a boundary that catches autumn sun.
- Put in late bulbs at least 7.5cm (3in) deep and bury chicken wire just below the surface to avoid them being eaten by squirrels.
- Feed resident birds with high energy supplements such as fat balls.

# WINTER

## THE KITCHEN GARDEN

### VEGETABLES

#### EARLY WINTER
- Hoe between crops on fine days.
- Examine stored onions and potatoes for any sign of disease and discard second-class seed. Any potatoes that are sprouting should be placed apart in dry trays.
- Protect more tender plants with leaves or cloches.
- Begin forcing rhubarb and seakale under a light-proof cover.
- Order seed catalogues and plan the new season's crops.

#### MID-WINTER
- Tidy up and put vegetable waste on the compost heap.
- Hoe between growing crops when dry.
- Sow broad (fava) beans and peas in warm sheltered positions.
- Sow early vegetables under glass or cloches.
- Start potatoes in a frost-free shed.
- Plant rhubarb in well-manured beds.

#### LATE WINTER
- Hoe weeds when the weather allows.
- Clear old beds ready for new season.
- Cut pea and bean sticks.
- Sow early vegetables under glass or cloches.
- Plant artichokes, garlic, shallots, lettuce (winter), potatoes (early), rhubarb and seakale.
- Plants overwintering under cloches should be hardened off and only protected when the weather is frosty.

### FRUIT

#### EARLY WINTER
- Finish pruning fruit trees and bushes on frost-free days. Large standard trees will need pruning every second or third year.
- Firm newly planted trees where the frost has been at work.
- Do not plant any more trees until the spring; just prepare the ground.
- Currants and gooseberries should be pruned if not already done.
- Prune outdoor vines.
- Remove unwanted suckers from raspberry stools but do not prune until early spring.

#### MID-WINTER
- Start pruning hardier trees such as apples. Do not prune apricots, cherries, figs, nectarines and peaches.
- Prepare grafting material.
- Plant container-grown trees and cover soil with well-rotted manure.

#### LATE WINTER
- Prune damsons, pears, plums and quince.
- Spread manure around fruit trees and dig it in.
- Prepare new strawberry beds.
- Fertilize by hand the blossom of fruit trees grown under glass.

### HERBS

#### EARLY WINTER
- Prepare ground for planting when conditions allow.
- Protect tender herbs under cloches.
- Continue to remove dead stems from herbaceous types.

#### MID-WINTER
- Prepare ground ready for planting.
- Force early growth under cloches.
- Make early sowings under glass.

#### LATE WINTER
- Remove dead stems from herbaceous types.
- Continue forcing under cloches.
- Continue sowing under glass.

# SPRING

#### EARLY SPRING
- Hoe weeds when the weather allows.
- Prepare seedbeds.
- Protect early crops from birds.
- Begin sowing in sheltered places in the open.
- Sow early vegetables under glass or cloches.
- Plant out early crops raised under glass and early potatoes.
- Plant early broad (fava) beans out in the garden under glass.

#### MID-SPRING
- Hoe weeds regularly.
- Prepare beds for planting out.
- Feed cabbages with high-nitrogen fertilizer such as chicken manure.
- Potatoes need the soil drawn over their leaves to protect them from frost.
- Begin sowing remaining summer crops outdoors.
- Continue sowing more tender crops under glass.

#### LATE SPRING
- Hoe weeds regularly.
- Cut asparagus when shoots reach 15cm (6in).
- Maintain the succession of seed sowing to give salad throughout the summer season.
- Continue planting out summer crops.
- Sow late crops such as broccoli and plant out winter crops previously sown under cover.
- Last chance to plant late potatoes.
- Plant out cucumbers, pumpkins and melons in beds previously used for protected early crops.

#### EARLY SPRING
- Protect blossom with fleece on cold nights.
- Last chance to plant container-grown fruit bushes.
- Graft apples, cherries, pears and plums that were prepared in mid-winter.
- Finish pruning fruit trees and bushes.

#### MID-SPRING
- Continue protecting blossom.
- Wall trees will need moisture from now on.
- Watch for pests and diseases.
- Grapes will require thinning in order to swell their size.

#### LATE SPRING
- All fruit will benefit from a mulch.
- Apricots, peaches and Morello cherries should have fruiting spurs shortened back to three to four leaves.
- Limit raspberry suckers to around four to six to each stool.
- Put straw around strawberries to protect the fruits from the ground.

#### EARLY SPRING
- Continue sowing under glass.
- Plant out hardy herbs once hardened off.
- Prune shrubby types.
- Lift and divide herbaceous types until late spring.

#### MID-SPRING
- Continue sowing under glass.
- Continue planting out.
- Take basal cuttings.

#### LATE SPRING
- Sow herbs like parsley (*Petroselinum crispum*) and chervil (*Anthriscus cerefolium*) for winter use.
- Continue sowing under glass and planting out.

# SUMMER

### EARLY SUMMER
- Hoe weeds regularly throughout summer.
- Water all salad crops regularly.
- Feed heavy feeders like cauliflowers with liquid manure or compost tea.
- Keep picking peas to stimulate flowering.
- Harvest early potatoes and replace with winter turnips or late celery.
- Support runner beans.
- Sow the last of the outdoor salad crops and continue sowing seed of late or winter crops.
- Thin out seedlings.
- Plant late-season crops raised under cover.

### MID-SUMMER
- Water all salad crops regularly.
- Remove debris, following harvest, to the compost heap until late summer.
- Potatoes and other crops may need earthing-up.
- Pinch out and stop tomatoes and marrows.
- Maintain the succession of seed sowing for late or winter crops.
- Thin out the beetroot crop so that the roots can form properly.
- Plant late-season crops raised under cover.

### LATE SUMMER
- Water all crops regularly.
- Remove debris, following harvest, to the compost heap.
- Harvest seed from French (green) beans and onions.
- Garlic and onions can be harvested this month and then ripened.
- Potatoes for next year's seed should be dug up and dried in the sun.
- Maintain the succession of seed sowing for late or winter crops.

# AUTUMN

### EARLY AUTUMN
- Hoe weeds regularly throughout autumn.
- Water all crops regularly.
- Harvest onions and bend down the necks of the remainder to prevent seeding.
- Continue to lift potatoes.
- Expose the fruit of outdoor tomatoes to the sun by removing the covering leaves.
- Maintain the succession of seed sowing for late or winter crops.
- Plant late season crops raised under cover.

### MID-AUTUMN
- After beans and peas have been harvested, turn the soil over and leave it fallow over the winter.
- Lift root vegetables when their tops fade.
- Cut down asparagus foliage when mature.
- Onions and turnip beds should be thinned.
- Clear the last of the potatoes and store them.
- Earth up celery and leeks.
- Plant out late-season crops and protect tender types such as cauliflower.

### LATE AUTUMN
- Get the soil ready for spring sowing.
- Protect crowns of tender crops with a mulch of leaves.
- Lift the last of the beetroot and carrots.
- Earth up celery and leeks if not already done.
- Spinach will continue to crop as it is thinned.
- Dry off the late potatoes for seed stock next year.
- Continue to plant out late-season crops and protect tender types such as cauliflower.

### EARLY SUMMER
- Continue mulching trees and bushes to conserve moisture.
- Cut back untidy vigorous growth.
- Over-laden trees may need support. Aphids will appear, so take appropriate action.
- Throw nets over fruiting trees and shrubs to prevent the birds getting the fruit first.
- Peaches and apricots may need some thinning.
- Strawberries should have regular watering.

### MID-SUMMER
- Thin trees and remove unnecessary growth.
- Hoe round the roots of fruit trees and water them.
- Fruit trees may be budded when the weather is moist.
- Espalier and dwarf fruit trees will need training and protection from birds.
- Strawberries and loganberries should be layered and clipped to the soil to secure their position.

### LATE SUMMER
- Protect fruit on walls from wasps and birds as it ripens.
- Pruning can be started and trees budded.
- Apples, pears and plums may need the fruit thinning out if the crop is heavy.
- Cut down the old canes of loganberries and raspberries after harvesting.
- Cut off unwanted runners from strawberries and remove the old straw from round the crowns.

### EARLY AUTUMN
- Wall fruit that has ripened will need protecting.
- Fruit trees may be budded and light pruning continued.
- Early varieties of apples and pears that do not keep well should be gathered.
- Prune currants and gooseberries to keep them in shape. Raspberry canes that have fruited should be removed to make room for the new growth.
- Strawberries should have unwanted runners removed to give space to the main plants.

### MID-AUTUMN
- Look though the nursery catalogues and order fruit stock, then prepare the ground and remove stock to be replaced.
- Move any trees or bushes that are in the wrong place.
- Apples and pears can now be gathered.
- Apricots, cherries, currants and gooseberries should be pruned and the cuttings burnt.
- Loganberries and raspberries should be planted now.

### LATE AUTUMN
- This is the time to plant fruit trees in well-prepared ground.
- Begin winter pruning of fruit trees.
- Plant currants and gooseberries.
- Figs will need thinning.
- Spread manure between rows of new strawberry plants.

### EARLY SUMMER
- Continue sowing under glass.
- Continue planting out until late summer.
- Harvest herbs for storing before they flower.
- Plant out tender herbs.
- Dead-head unless seed is required until late summer.
- Cut back herbaceous types to stimulate growth until late summer.

### MID-SUMMER
- Cut mint (*Mentha*) and other sweet herbs for drying.
- Pull out parsley (*Petroselinum crispum*) unless it is being kept for seed.
- Propagate sage (*Salvia*) or savory (*Satureja*) from cuttings or division.

### LATE SUMMER
- Harvest herbs as required.

### EARLY AUTUMN
- Harvest seed as it ripens.
- Harvest leaves and stems as required.
- Cut back herbaceous types to stimulate new growth.

### MID-AUTUMN
- Harvest seed as it ripens.
- Tidy away dead material.
- Protect tender herbs.
- Plant shrubby and herbaceous types until late autumn.
- Move tender container herbs under some protection.
- Divide herbaceous herbs until late autumn.

### LATE AUTUMN
- Prepare ground for planting when conditions allow.

# ACKNOWLEDGEMENTS

**Authors' Acknowledgements**

We would like to thank the following people who worked as models for the photography: Joe Lovell, Debbie Hart for her willow weaving skills, Jane Dobson for her graft unions and Ian Gandy and Stewart Brown for the lawn maintenance shots. A big thank you to Writtle College and their staff for allowing the use of their grounds and glasshouses to take many of the photographs.

**Publisher's Acknowledgements**

The publisher would like to thank the following for kindly allowing photography to take place in their gardens:
t = top b = bottom l = left r = right c = centre

# Declare Your Independence

**The world seems to be growing in complexity every day.** While much of today's new technology makes legitimate improvements in our lives, this new electronic age has created something of a backlash. Each upgraded cellphone generation and ever-spreading factory farm distances us just a little bit farther from the days when all you needed to conquer the world was a tillable acre and a mule. The projects in this book are designed to help you close that widening gap—if only just a bit.

**Self-Sufficiency vs. Green**

People who are interested in adopting a more self-sufficient lifestyle almost certainly subscribe to today's Green principles and to an approach to living based on stewardship. It is worth noting, however, that the projects described in this book were chosen because they result in a product, usually a consumable, that contributes directly to the pool of things you and your family need in order to live—and live well.

The decisions we make every day—even down to which grain was used to make the flour in your morning toast—are part of a chain of thousands of other decisions that, taken together, have a profound effect on the resources of our planet and the health and prosperity of our families. The urge to take back some control of our own lives and futures has never been stronger.

The good news is: You can. Whether you live in a bustling city, sprawling suburban development, or rural estate, you can achieve greater everyday self-sufficiency with relatively little effort. As self-sufficiency expert John Seymour wrote, "You do not need five acres and a degree in horticulture to become self-sufficient ... self-sufficiency is about taking control and becoming an effective producer of whatever your resources allow."

*DIY Projects for the Self-Sufficient Homeowner* provides you with around two dozen ways to help you maximize your resources and participate in the march toward greater self-reliance. Whether you own a small balcony downtown or a couple of acres in the suburbs, you can grow much more of your own food than you ever expected—as long as you have the right tools, such as raised garden beds, compost bins, container gardens, or even a small greenhouse. Whether you have an expansive estate or a small

backyard, you can raise animals—this book will show you how to build a chicken coop, a beehive, and animal-friendly fencing. It contains many more projects related to the production and storage of food from your own homestead.

**Solar panels that** collect and heat air to warm cold spaces in your home are mechanisms you can build yourself and duct in to your home's existing ductwork. Learn how on page 147.

But raising your own food is not the only way to increase your self-reliance. With new DIY-friendly technology, generating your own clean energy is easier than ever. Here, you'll see exactly how to build a solar panel, install solar energy systems, and understand alternative energy sources.

The key to your self-sufficiency is to focus first on a few doable projects that fit into your lifestyle without a lot of adjustments. Most modern homeowners will not be able to maintain a fully self-sufficient home without quitting their day job, and that shouldn't necessarily be the goal for everyone. All homeowners can, however, take steps toward greater self-reliance, and partake in the satisfaction that comes from providing for your family's needs through your own effort. So get started: The time has never been better to declare your independence.

## The Self-Sufficient Lifestyle

Self-sufficient living is a highly complementary practice—once you begin, you'll find that many parts of your home are connected, and that multiple systems of self-sufficiency contribute to one another, often corresponding with the natural cycles of the earth. Because of this interconnectedness, many of the projects in this book will naturally lead you to more and more projects that will help you maximize your self-sufficiency work.

**Building a greenhouse** is a great way for gardeners to jump-start the growing season, or to introduce new, sensitive plants to your garden. See page 59.

For example, if you start a garden, the fruits and vegetables you grow will provide waste that will transform into the compost that will nurture next year's bounty. Setting up a rainwater collection system not only reduces your reliance on public utilities, the fresh, soft water will help your plants grow healthy. The hens you are raising for their eggs control garden pests and provide free fertilizer. At the end of the growing season, you'll likely be overwhelmed with vegetables, and will need to find a means to store and preserve them—perhaps a basement root cellar could be a good option. And, by growing organic vegetables nurtured by compost and animal manure, you create a pesticide-free habitat for honeybees to prosper, while they, in turn, pollinate the plant life.

That said, you do not need to take on all the projects in this book at once. Start with the projects that naturally supplement the efforts your family is already making toward self-sufficiency. If you already recycle, a natural next step is to build compost bins and begin to make compost with food and paper waste as well. If you already maintain a beautiful flower garden, why not build a home for the honeybees that are already frequent visitors, allowing you to collect the honey they produce? If you need to connect electricity to an outbuilding or shed that is not currently grid-connected, why not install solar panels instead of wiring the building into the grid? If you already garden, why not build a greenhouse?

For the newcomer, the projects on the following pages provide multiple opportunities to create a more self-reliant lifestyle. For the experienced self-sufficient homeowner, the step-by-step projects included here will provide you with the means to expand and streamline your efforts.

## Efficiency, Conservation & Recycling

If increased self-sufficiency is your goal, paying attention to the efficiency with which you use your resources is common sense. For example, if your goal is to use solar-heated air to heat all or part of your home, it makes sense that you want every bit of the heat your solar panels produce to contribute to the temperature of the room, instead of being lost through drafty windows or poorly insulated walls. Investing in energy-efficient windows and doors and properly insulating your home is a very important step in the implementation of an alternate or supplementary heating system.

If one of the goals of your self-sufficient lifestyle is to decrease your utility bills, a key first step that is often overlooked is resource conservation, which can make a huge and immediate impact on your utility bills. For example, before you invest in a gray water recycling system or install a cistern for rainwater collection to lessen your dependence on water provided by utility companies, coach your family in water conservation practices. Run the dishwasher only when it is full, wash only full loads of laundry, turn off the tap when brushing your teeth, and focus on taking shorter, more efficient showers.

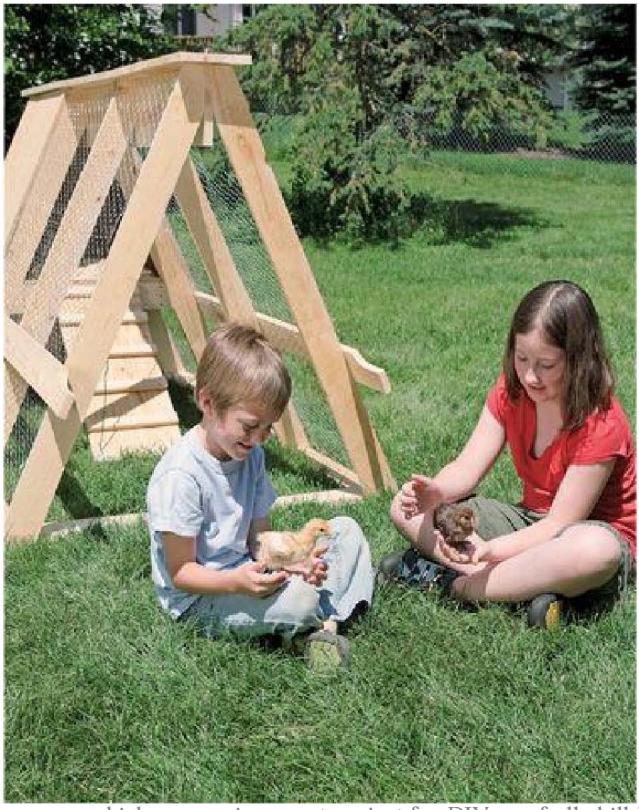
**The best resources** are the ones you already own. Re-using or repurposing stuff you no longer need takes some creativity, but ultimately it fills needs, not landfills. For example, this discarded dressing table found new life as a vanity cabinet in a self-sufficient homeowner's bathroom.

Increasing your own awareness of how to reuse the objects around you to benefit your self-sufficient living projects will also contribute to your success as a self-sufficient homeowner. If you plan to start your own seedlings each year, you'll need planting containers. Why not reuse plastic yogurt cups or other food containers you've already used instead of purchasing new containers? One of the nuggets of wisdom modern self-reliant homeowners must adopt is that objects do not need to be as disposable as we are led to believe. Find a way to repurpose the objects you buy, compost paper and food waste, and ensure that your tools, buildings and appliances are properly maintained to ensure that they enjoy a long and useful life in your home.

## Getting Started

A key factor in finding your starting point is to develop an understanding of your goals as a self-sufficient homeowner. Self-sufficiency can contribute to many different aspects of your family's lifestyle. So before you plot out your projects, consider the tenets of self-sufficiency, as described below, and define what being self-sufficient means to you.

**Producing Your Own Food:** This is unquestionably the most involved aspect of a self-sufficient lifestyle for many homeowners —urban, suburban, and rural. Consider how food production and storage can ft into your home, whether you plan to start a garden or build a greenhouse, raise chickens and other small animals, build a root cellar for winter produce storage, or raise honeybees.



**Building your own** chicken coop is a great project for DIYers of all skill levels (see page 115). chickens provide nutritious eggs, natural garden pest-control, and organic fertilizer.

**Saving on Utility Costs:** Independence from local energy sources is another major draw for self-reliance enthusiasts. Whether you seek independence from utility companies because of prohibitive costs, unreliable service, or your own desire to live off the grid, many of the projects in this book can help you take first steps to get there. Bear in mind, however, that many energy- or utility-production systems do require a significant financial investment in the beginning, but will pay for themselves within the first ten years of use.

**Producing Clean Energy:** Many self-sufficient homeowners are more motivated by their desire to produce energy for their homes with little or no impact on the environment than they are by utility company bills. Producing non-polluting, renewable energy is increasingly achievable for residential homeowners as technological advances make the necessary equipment affordable, accessible, and easy to install.

**Conserving Resources and Creating Less Waste:** Conserving the earth's resources and minimizing waste is a practice that goes hand-in-hand with a self-sufficient lifestyle.

**Collected rainwater** is perfect for watering the garden or the lawn. Rain is soft and free of most pollutants, so it is perfect for plant irrigation. Learn how to make your own rain barrels—flip to page 13.

**Drying produce** is one way to preserve the fruits of your labor, so you can enjoy your garden's bounty through the winter months. Learn how to build a simple solar food dryer on page 86.

**Even if you don't have** a lot of space, you can use any sunny spot to grow produce in containers. A strawberry barrel like this can house up to 25 feet of strawberry plants and only takes up 2 square feet of space. To make your own barrel, see page 46.

DIY Projects

# Collecting Rainwater

**Practically everything around your house that requires water** loves the natural goodness that's provided with soft rainwater. With a simple rain barrel, you can collect rainwater to irrigate your garden or lawn, water your houseplants, or top off swimming pools and hot tubs. A ready supply of rainwater is also a reliable stand-by for emergency use if your primary water supply is interrupted.

**Rainwater that is collected** in a rain barrel before it hits the ground is free of many contaminants that water picks up as it filters through soil. This soft, warm (and free) water is perfect for plants, lawns, and many other outdoor applications.

Collecting rainwater runoff in rain barrels can save thousands of gallons of tap water each year. A typical 40 × 40-ft. roof is capable of collecting 1,000 gallons of water from only one inch of rain. A large rainwater collection system that squeezes every drop from your roof can provide most—or sometimes all—of the water used throughout the home, if it's combined with large cisterns, pumps, and purification processing.

Sprinkling your lawn and garden can consume as much as 40 percent of the total household water use during the growing season. A simple rain barrel system that limits collected water to outdoor (nonpotable) use only, like the rain barrels described on the following pages, can have a big impact on the self-sufficiency of your home, helping you save on utility expenses and reducing the energy used to process and purify water for your lawn and garden. Some communities now offer subsidies for rain barrel use, offering free or reduced-price barrels and downspout connection kits. Check with your local water authority for more information. Get smart with your water usage, and take advantage of the abundant supply from above.

## Rain Barrels

Rain barrels, either built from scratch or purchased as a kit, are a great way to irrigate a lawn or garden without running up your utilities bill. The most common systems include one or more rain barrels (40 to 80 gallons) positioned below gutter downspouts to collect water runoff from the roof. A hose or drip irrigation line can be connected to spigot valves at the bottom of the rain barrel. You can use a single barrel, or connect several rain barrels in series to collect and dispense even more rainwater.

Plastic rain barrel kits are available for purchase at many home centers for around $100. If kit prices aren't for you, a rain barrel is easy to make yourself for a fraction of the price. The most important component to your homemade barrel is the drum you choose.

## Obtaining a Barrel

Practically any large waterproof container can be used to make a rain barrel. One easily obtained candidate is a trash can, preferably plastic, with a snap-on lid. A standard 32-gallon can will work for a rain barrel, but if you can find a 44-gallon can choose it instead. Although wood barrels are becoming more scarce, you can still get them from wineries. A used 55-gallon barrel can be obtained free or for a small charge from a bulk food supplier. Most 55-gallon barrels today are plastic, but some metal barrels are still floating around. Whatever the material, make sure the barrel did not contain any chemical or compound that could be harmful to plants, animals, or humans. If you don't know what was in it, don't use it. Choose a barrel made out of opaque material that lets as little light through as possible, reducing the risk of algae growth.

A barrelful of water is an appealing breeding ground for mosquitoes and a perfect incubator for algae. Filters and screens over the barrel opening should prevent insect infestation, but for added protection against mosquitoes add one tablespoon of vegetable oil to the water in the barrel. This coats the top surface of the stored water and deprives the larvae of oxygen.

## TOOLS & MATERIALS

Barrel or trash can
drill with spade bit
Jigsaw
Hole saw
Barb fitting with nut for overflow hose
1-1/2" sump drain hose for overflow
3/4" hose bibb or sillcock
3/4" male pipe coupling
3/4" bushing or bulkhead connector
Channel-type pliers
Fiberglass window screening
Cargo strap with ratchet
Teflon tape
Silicone caulk

# How to Make a Rain Barrel

**1 Cut a large opening** in the barrel top or lid. Mark the size and shape of your opening —if using a bulk food barrel, mark a large semi-circle in the top of the barrel. If using a plastic garbage can with a lid, mark a 12"-dia. circle in the center of the lid. Drill a starter hole, and then cut out the shape with a jigsaw.

**2 Install the overflow hose.** Drill a hole near the top of the barrel for the overflow fitting. Thread the barb fitting into the hole and secure it to the barrel on the inside with the retainer nut and rubber washer (if provided). Slide the overflow hose into the barbed end of the barb elbow until the end of the hose seats against the elbow flange.

**3 Drill the access hole** for the spigot (either a hose bibb or sillcock brass or PVC). Tighten the stem of the sillcock onto a threaded coupling inserted into the access hole. Inside the barrel a rubber washer is slipped onto the coupling end and then a threaded bushing is tightened over the coupling to create a seal. Apply a strip of Teflon tape to all threaded parts before making each connection. Caulk around the spigot with clear silicone caulk.

**4 Screen over the opening** in the top of the barrel. Lay a piece of fiberglass insect mesh over the top of the trash can and secure it around the rim with a cargo strap or bungee cord that can be drawn drum-tight. Snap the trash can lid over the top. Once you have installed the rain barrel periodically remove and clean the mesh.

# How to Install a Rain Barrel

Whether you purchase a rain barrel or make your own from scratch or a kit, how well it meets your needs will depend on where you put it and how it is set up. Some rain barrels are temporary holding tanks that store water runoff just long enough to direct it into your yard through a hose and drip irrigation head. Other rain barrels are more of a reservoir that supplies water on-demand by filling up watering cans or buckets. If you plan to use the spigot as the primary means for dispensing water, you'll want to position the rain barrel well off the ground for easy access (raising your rain barrel has no effect on water pressure).

In addition to height, other issues surrounding the placement of your rain barrel (or rain barrels) include the need to provide a good base, orientation of the spigot and overflow, the position relative to your downspouts, and how to link more than one rain barrel together. **TIP**: Wherever possible, locate your rain barrel in a shaded area. Sunlight encourages algae growth, especially in barrels that are partially translucent.

## TOOLS & MATERIALS

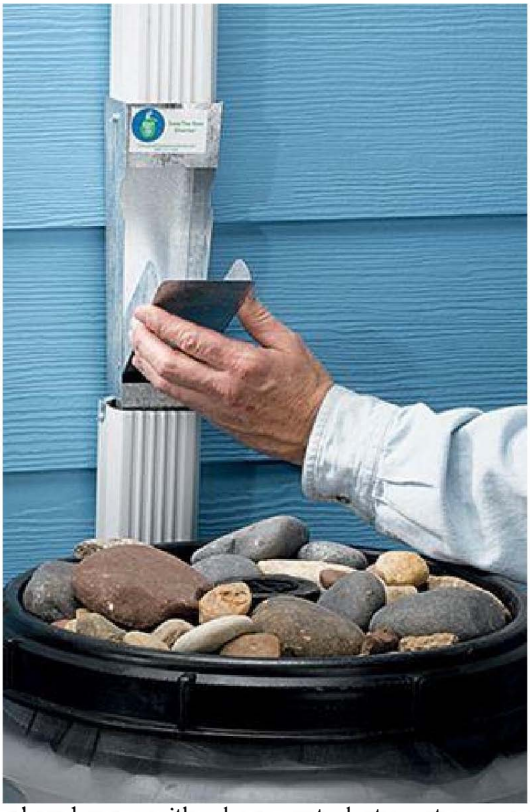
Drill/driver
Screwdriver
Hack saw
Rainbarrel
Hose & fittings
Base material (pavers)
Downspout adapter and extension
Teflon tape

**1 Select a location** for the barrel under a downspout. Locate your barrel as close to the area you want to irrigate as possible. Make sure the barrel has a stable, level base.

**2 Install the spigot**. Some kits may include a second spigot for filling watering cans. Use Teflon tape at all threaded fittings to ensure a tight seal. Connect the overflow tube, and make sure it is pointed away from the foundation.

**3 Cut the downspout** to length with a hacksaw. Reconnect the elbow fitting to the downspout using sheet-metal screws. Attach the cover to the top of the rain barrel. Some systems include a cover with porous wire mesh, to which the downspout delivers water. Others include a cover with a sealed connection (next step).

**4 Link the downspout** elbow to the rain barrel with a length of flexible downspout extension attached to the elbow and the barrel cover.



**Variation:** If your barrel comes with a downspout adapter, cut away a segment of downspout and insert the adapter so it diverts water into the barrel.

**5 Connect a drip** irrigation tube or garden hose to the spigot. A Y-fitting, like the one shown here, will let you feed the drip irrigation system through a garden hose when the rain barrel is empty.

**6 If you want,** increase water storage by connecting two or more rain barrels together with a linking kit, available from many kit suppliers.

2

# Collecting Gray Water

**Gray water is a term used to describe wastewater from your** water source that is free of contaminants like toilet waste and garbage disposal remains. Water that has come into contact with these types of contaminants is referred to as “black water” and its reuse is strictly prohibited for public health reasons. Wastewater generated directly from the tap (usually while you’re waiting for the tap water to heat up or cool down) contains very few or no contaminants, such as soap, cleaning chemicals, food waste, or other added organic and inorganic material.

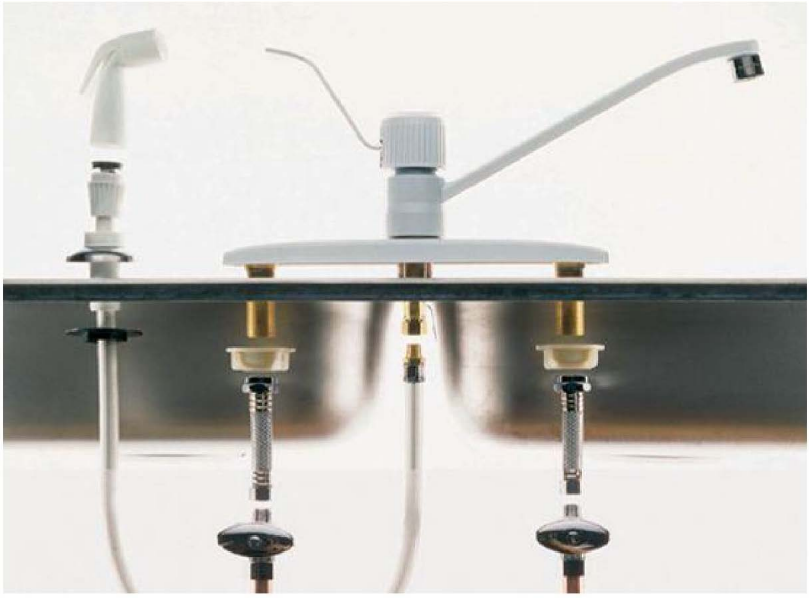
**A small gray water** recovery sink that drains automatically to a reservoir makes it easy to reuse gray water for watering plants or gardens. Gray water systems like this make it easy to recycle thousands of gallons of clean tap water each year.

Gray water can be collected easily and used for many household purposes without treatment or filtration. It is not suitable for consumption, however. Gray water that contains some contaminants, such as laundry suds, dish soap, or shower/bath water can be used for some limited purposes, such as flushing toilets.

A simple way to capture gray water for reuse is to install a diverter in the form of a small sink basin and drain. Instead of leading to the sewer, the diverter's drain is directed to a closed receptacle, usually in the basement or outdoors. The captured water can be used for watering plants or the lawn. To avoid allowing bacteria to fester in the gray water receptacle, do not allow the water to stagnate.

**Removing a Sprayer**

Remove your old sink sprayer to clear an opening for the diverter sink in your sink deck. The hose that supplies the sprayer usually is attached to the base of the faucet valve. You'll need to disconnect it and tighten a screw-on tube cap onto the bottom of the tube.

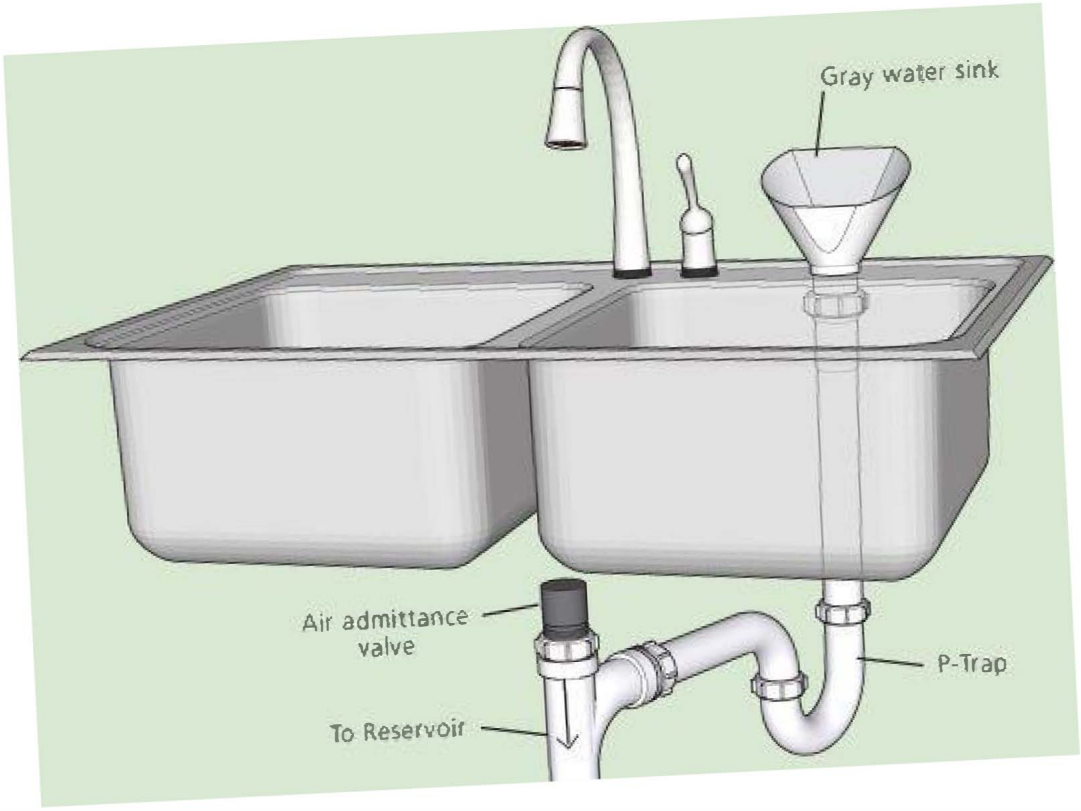


The gray water collection sink seen in this project is a fairly simple technology. Advanced recovery systems are designed to help you reuse wastewater of many types. They are complex and can involve double-plumbing throughout parts of your home, along with water purification processes and chemicals, holding tanks, plumbing switches, pumps, subsurface irrigation systems, and other components. If you're committed to reusing as much water as you can for as many purposes as possible, hire a professional to design the best system for your family's needs.

## Installing a Gray Water Recovery Sink

The Envirosink gray water diverter apparatus installed in this project is available for sale online and from "Green" home retailers (See Resources, page 158.) It is designed to be mounted in a kitchen sink deck knockout—usually the one reserved for the sprayer or the soap dispenser. It can be used with any kitchen faucet—you simply spin the faucet to empty into the diverter.

Once it is diverted from the sink drain by the collection sink, the gray water is directed through a hose to a reservoir from which it can be dispensed easily for general household use. The reservoir should be a sealed tank with an overflow fitting that leads to the home drain/waste system (if indoors) or a well-drained runoff area (if outdoors). The plumbing for the runoff system should include a P-trap and an air admittance valve (or other backflow preventer).



Gray water sink
Air admittance valve
P-Trap
To Reservoir

## TOOLS & MATERIALS

Drill
Eye protection
Gray water sink kit
(See resources, page 158)
Caulk
1/8" rubber washer
Flange nut
Clean rag
1-1/2"-dia. drain tubes
Power miter saw or ratcheting
plastic-pipe cutter
Solvent glue
Large bucket

# How to Install a Gray Water Diverter Sink

**1 Choose the best spot** for the diverter sink to be mounted. Usually, this means taking over an unused knockout in your sink deck or removing a sprayer or soap dispenser. Otherwise, you can drill a hole for the diverter as close as possible to the diverter.

**2 Attach the diverter sink's drain tailpiece** to the sink deck or countertop. Apply a small bead of kitchen and bath caulk around the edges of the hole and press the tailpiece flange into the caulk. From below, slip a 1/8" rubber washer onto the tailpiece and then hand-tighten a flange nut.

**3 Assemble the sink drain system** completely before installing it as a unit. Here, an air admittance valve is being solvent-glued to a drain stub from the drain P-trap. You'll need to run additional drain pipe to supply water to your reservoir. Contact a plumbing professional if you do not have experience with home plumbing.

**4 Hook up the drain assembly** to the tailpiece from the diverter sink. Run drain pipe to your water storage reservoir tank, making sure the tank is equipped with an overflow valve and tubing that leads into the main drain system.

3

# Composting

**The byproducts of yard maintenance and food preparation** accumulate rapidly. Everyday yardcare alone creates great heaps of grass clippings, trimmings, leaves, branches, and weeds. Add to this the potato peelings, coffee grounds, apple cores, and a host of organic kitchen leavings. The result is a large mass of organic matter that is far too valuable a resource to be simply dumped into the solid waste stream via curbside garbage collection. Yard waste and kitchen scraps can be recycled into compost and incorporated back into planters or garden beds as a nutrient-rich (and cost-free) soil amendment.

**Composting turns yard waste** and kitchen scraps into a valuable soil amendment.

**Managed Composting**

With the right conditions, you can speed up Mother Nature's course and yield several helpings of fresh compost for your yard each season. This is called managed composting, as opposed to passive composting, when you allow a pile of plant debris and such to decompose on its own. The conditions must be just right to manage compost and speed the process. You'll need a balance of carbon and nitrogen, the right temperature, good air circulation, and the right amount of water. By mixing, chopping materials, and monitoring conditions in your compost pile, you'll increase your yield each season.

Compost is nature's own potting soil, and it effectively increases soil porosity, improves fertility, and stimulates healthy root development. Besides, making your own soil amendment through composting is much less expensive than buying commercial materials.

So how does garbage turn into plant food? The process works like this: Organisms such as bacteria, fungi, worms, and insects convert compost materials into humus, a loamy, nutrient-rich soil. Humus is the end goal of composting. Its production can take a couple of years if left undisturbed, or it can be sped up with some help from your pitchfork and a little livestock manure.

Although composting occurs throughout nature anywhere some organic matter hits the earth, in our yards and gardens it is always a good idea to contain the activity in a designated area, like a compost bin. Functionally, there are two basic kinds of bins: multi-compartment compost factories that require a fair amount of attention from you and hidden heaps where organic matter is discarded to rot at its own pace. Both approaches are valid and

both will produce usable compost. The main compost bin project seen on p. 28 is an example of the more passive style. At roughly one cubic yard in volume, it can handle most of your household organic waste and some garden waste. If you have a higher volume of organic waste or want to use a three-bin approach to staged composting, simply build additional bins.

## Compost Variables

**Air:** The best microbes for decomposing plant materials are aerobic, meaning they need oxygen. Without air, aerobic microbes die and their anaerobic cousins take over. Anaerobic microbes thrive without oxygen and decompose materials by putrefaction, which is smelly and slow. Your goal is aerobic activity, which smells musty and loamy, like wet leaves. Improve air circulation in your compost bin by ensuring air passageways are never blocked. Intersperse layers of heavier ingredients (grass clippings, wet leaves) with lighter materials like straw, and turn the pile periodically with a garden fork or pitchfork to promote air circulation.

**Water:** Compost should be as wet as a wrung-out sponge. A pile that's too wet chokes out necessary air. A too-dry pile will compost too slowly. When adding water to a compost pile, wet in layers, first spraying the pile with a hose, then adding a layer of materials.

**Temperature:** A fast-composting pile produces quite a bit of heat. On a cool morning, you might notice steam rising from the pile. This is a good sign. Track the temperature of your pile and you'll know how well it's progressing. Aim for a constant temperature between 140 and 150 degrees Fahrenheit, not to exceed 160 degrees. To warm up a cool pile, agitate it to increase air circulation and add nitrogen-dense materials like kitchen waste or grass clippings. A pile about three feet high and wide will insulate the middle of the pile and prevent heat from escaping. You'll know the compost process is complete when the pile looks like dirt and is no longer generating extraordinary heat.

**Called "black gold"** by home gardeners, compost can be generated on-site and added to any planting bed, lawn, or container for a multitude of benefits. Sifting the compost before you introduce it to your yard or garden is recommended.

## Browns and Greens

A fast-burning compost pile requires a healthy balance of "browns" and "greens." Browns are high in carbon, which food energy microorganisms depend on to decompose the pile. Greens are high in nitrogen, which is a protein source for the multiplying microbes. A ratio of three-to-one brown-to-green materials is a good target.

**Browns:** Dry brown plant material, straw, dried brown weeds, wood chips, some saw dust (use with caution—avoid saw dust from chemically treated wood)

**Greens:** Grass clippings, kitchen fruit and vegetable scraps, green leaves, and manure

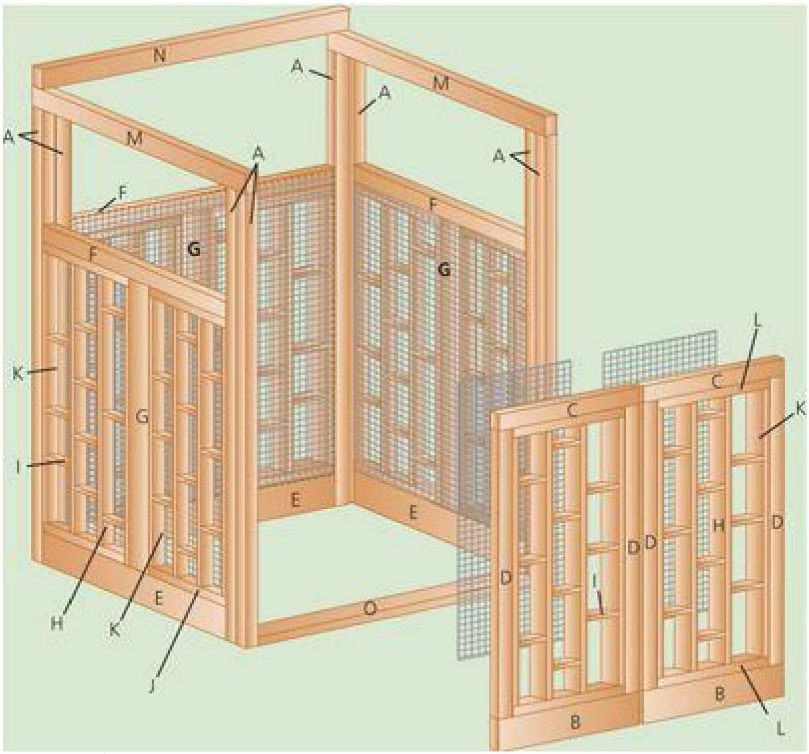
**Note:** If you use chemical lawn care products on your lawn, do not include grass clippings in your compost pile.

## Building a Compost Bin

### CUTTING LIST

| Key | Part | No. | Dim. | Material |
|---|---|---|---|---|
| A | Post | 8 | 1½ × 1¾ × 48" | Cedar |
| B | Door rail | 2 | 1½ × 3½ × 16" | " |
| C | Door rail | 2 | 1½ × 1¾ × 16" | " |
| D | Door stile | 4 | 1½ × 1¾ × 30½" | " |
| E | Panel rail | 3 | 1½ × 3½ × 32½" | " |
| F | Panel rail | 3 | 1½ × 1¾ × 32½" | " |
| G | Panel stile | 3 | 1½ × 3½ × 30½" | " |
| H | Infill | 16 | ¾ × 1½ × 30½" | " |
| I | Filler | 80 | ¾ × 1½ × 4" | " |
| J | Panel grid | 12 | ¾ × 1½" × Cut to fit | |
| K | Grid frame-v | 16 | ¾ × 1½" × Cut to fit | Cedar |
| L | Door frame-h | 4 | ¾ × 1½" × Cut to fit | " |
| M | Top rail-side | 2 | 1½ × 1¾ × 39" | " |
| N | Top rail-back | 1 | 1½ × 1¾ × 32½" | " |
| O | Front spreader | 1 | 1½ × 3½ × 32½" | |

Also need:
1/2" galvanized hardware cloth 36" by 12 ft.
U-nails (fence staples)
2 pairs 2 × 2" butt hinges
2-1/2" deck screws
Exterior wood glue
Galvanized finish screws
Exterior wood sealant



**A compost bin** can be very plain, or it can have just enough decorative appeal to improve the appearance of a utility area.

# How to Build a Compost Bin

**1 Prepare the wood stock.** At most building centers and lumber yards, you can buy cedar sanded on all four sides, or with one face left rough. The dimensions in this project are sanded on all four sides. Prepare the wood by ripping some of the stock into 1-3/4"-wide strips (do this by ripping 2 × 4s down the middle on a tablesaw or with a circular saw and cutting guide).

**2 Cut the parts** to length with a power miter saw or a circular saw. For uniform results, set up a stop block and cut all similar parts at once.

**3 Assemble the door frames.** Apply exterior-rated wood glue to the mating parts and clamp them together with pipe or bar clamps. Reinforce the top joints with 3" countersunk deck screws (two per joint). Reinforce the bottom joints by drilling a pair of 3/8"-dia. × 1" deep clearance holes up through the bottom edges of the bottom rails and then driving 3" deck screws through these holes up into the stiles.

**4 Assemble the side and back panels.** Clamp and glue the posts and rails for each frame, making sure the joints are square. Then, reinforce the joints with countersunk 3" deck screws.

**5 Hang the door frames.** With the posts cut to length and oriented correctly, attach a door frame to each post with a pair of galvanized butt hinges. The bottoms of the door frames should be slightly higher than the bottoms of the posts. Temporarily tack a 1 × 4 brace across both door bottom rails to keep the doors from swinging during construction.

**6 Join the panels** and the door assembly by gluing and clamping the parts together and then driving 2-1/2" countersunk deck screws to reinforce the joints. To stabilize the assembly, fasten the 2 × 4 front spreader between the front, bottom edges of the side panels. Make sure the spreader will not interfere with door operation.

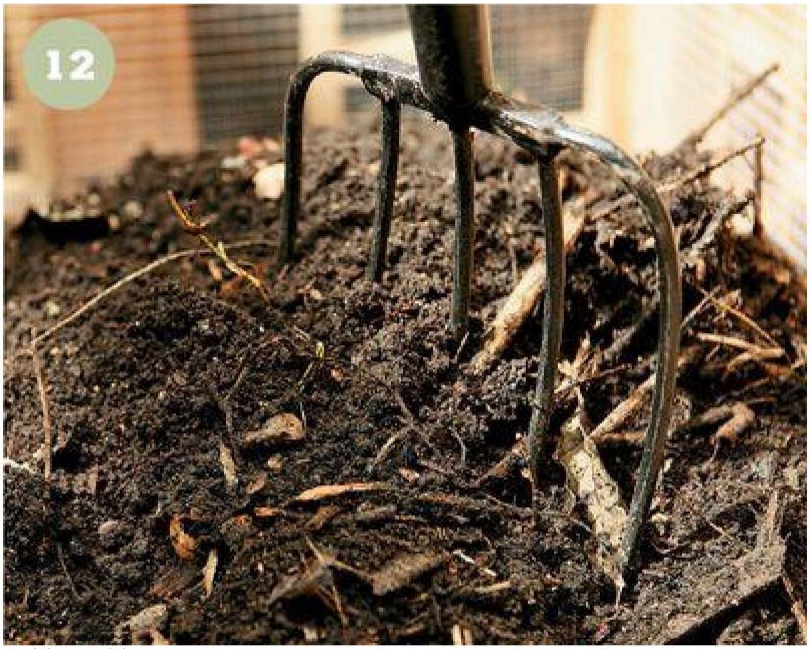
**7 Make the grids** for the panel infill areas. Use 1 × 2 cedar to make all parts. Use exterior glue and galvanized finish nails to connect the horizontal filler strips to the vertical infill pieces. Vary the heights and spacing of the filler for visual interest and to make the ends accessible for nailing.

**8 Frame the grids** with 1 × 2 strips cut to the correct length so each frame fits neatly inside a panel or door opening. Install the grid frames in the openings, making sure all front edges are flush.

**9 Attach the top rails** that conceal the post tops and help tie the panels together. Attach the sides first using exterior glue and galvanized finish nails. Then, install the back rail on top of the side rails. Leave the front of the project open on top so you can load, unload, and turn over compost more easily.

**10 Line the interior surfaces of** the compost bin with 1/2" galvanized hardware cloth. Cut the hardware cloth to fit and fasten it with fence staples, galvanized U-nails, or narrow-crown pneumatic staples (5/8" minimum) driven every 6" or so. Make sure you don't leave any sharp edges protruding. Grind them down with a rotary tool or a file.

**11 Set up the bin** in your location. It should not be in direct contact with any structure. If you wish, apply a coat of exterior wood sealant to all wood surfaces—use a product that contains a UV inhibitor. **TIP:** Before setting up your compost bin, dig a hole just inside the area where the bin will be placed. This will increase you bin's capacity.



**12 Add suitable organic matter** to the bin and turn with a pitchfork occasionally to speed up the rate of aerobic decomposition. With a little nurturing and good conditions, a compost bin can yield several batches of usable compost in a growing season.

## What to Compost, What Not to Compost

Vegetable plants soak up the materials that make up your compost, and these materials will play a vital role in the development of the vegetables that will grace your dinner table! When in doubt as to what should or shouldn't go into your compost pile for your garden, follow these general guidelines:

| Great Garden Compost | Not for Compost, Please |
|---|---|
| "Clean" food scraps—including crushed eggshells, corncobs, vegetable scraps, oatmeal, stale bread, etc. | Fatty or greasy food scraps—including meat waste, bones, grease, dairy products, cooking oils, dressings, sandwich spreads, etc. |
| Vegetable and fruit peelings and leftovers | Fruit pits and seeds—These don't break down well and can attract rodents. |
| Coffee grounds and filters, tea leaves and tea bags | Metal. Remove the tea bag staples before composting! |
| Old potting soil | Diseased plant material |
| Lawn clippings | Weeds—These will only sprout in your garden! Kill the weed seeds and salvage the compostable bits by baking or microwaving the plants before adding them to your compost bin. |
| Prunings from your yard, chopped up in small pieces | Big chunks of yard debris or plants that are diseased or full of insect pests |
| Shredded leaves and pine needles | Any plant debris that has been treated with weed killer or pesticides |
| Shredded newspaper and telephone books—black and white pages only | Glossy color ads or wax-coated book covers |
| White or brown paper towels and napkins | Colored paper towels and napkins |
| Wood ash—use sparingly | Coal ash |
| Cardboard | Pizza boxes or other wax-coated food boxes |
| Livestock manure | Cat, dog, or other pet waste, which may contain meat products or parasites |
| Sawdust, wood chips, and woody brush | Sawdust from wood treated with preservatives |
| Straw or hay—the greener, the better! | |
| Wilted floral bouquets | |

4

# Raised Beds

**Raised garden beds offer several advantages over planting at** ground level. When segregated, soil can be amended in a more targeted way to support high density plantings. Also, in raised garden beds, soil doesn't suffer compaction from foot traffic or machinery, so plant roots are free to spread and breathe more easily. Vegetables planted at high densities in raised beds are placed far enough apart to avoid overcrowding, but close enough to shade and choke out weeds. In raised beds, you can also water plants easily with soaker hoses, which deliver water to soil and roots rather than spraying leaves and inviting disease. And if your plants develop a fungus or another disorder, it is easier to treat and less likely to migrate to other plants in a raised bed situation.

**Raised garden beds** make great vegetable gardens—they're easy to weed, simple to water, and the soil quality is easier to control, ensuring that your vegetable plants yield bountiful fresh produce. Your garden beds can be built at any height up to waist-level. It's best not to build them much taller than that, however, to make sure you can reach the center of your bed.

**Bed Positions**

If you're planting low-growing crops, position the bed with a north-south orientation, so both sides of the bed will be exposed to direct sunlight. For taller crops, position the bed east-west.

Raised garden beds can be built in a wide variety of shapes and sizes, and can easily be customized to fit the space you have available on your property. Just make sure you can reach the center easily. If you can only access your raised bed from one side, it's best to build it no wider than 3 ft. Beds that you can access from both sides can be as wide as 6 ft., as long as you can reach the center. You can build your raised bed as long as you'd like.

Raised garden beds can be built from a wide variety of materials: 2× lumber, 4 × 4 posts, salvaged timbers, even scrap metals and other recycled goods. Make sure any lumber you choose (either new or salvaged) hasn't been treated with creosote, pentachlorophenol, or chromated copper arsenic (CCA). Lumber treated with newer, non-arsenate chemicals at higher saturation levels is rated for ground contact and is also a safe choice for bed frames. Rot-resistant redwood and cedar are good choices that will stand the test of time. Other softwoods, including pine, tamarack, and cypress, will also work, but can be subject to rot and may need to be replaced after a few years.

# Vegetable Plant Compatibility Chart

| Vegetable | Loves | Incompatible with | Planting Season |
|---|---|---|---|
| Asparagus | Tomatoes, parsley, basil | | Early spring |
| Beans (bush) | Beets, carrots, cucumbers, potatoes | Fennel, garlic, onions | Spring |
| Cabbage & broccoli | Beets, celery, corn, dill, onions, oregano, sage | Fennel, pole beans, strawberries, tomatoes | Spring |
| Cantaloupe | Corn | Potatoes | Early summer |
| Carrots | Chives, leaf lettuce, onion, parsley, peas, rosemary, sage, tomatoes | Dill | Early spring |
| Celery | Beans, cabbages, cauliflower, leeks, tomatoes | | Early summer |
| Corn | Beans, cucumbers, peas, potatoes, pumpkins, squash | | Spring |
| Cucumbers | Beans, cabbages, corn, peas, radishes | Aromatic herbs, potatoes | Early summer |
| Eggplant | Beans | Potatoes | Spring |
| Lettuce | Carrots, cucumbers, strawberries | | Early spring |
| Onions & garlic | Beets, broccoli, cabbages, eggplant, lettuce, strawberries, tomatoes | Peas, beans | Early spring |
| Peas | Beans, carrots, corn, cucumbers, radishes, turnips | Chives, | Early spring |
| Potatoes | Beans, cabbage, corn, eggplant, peas | Cucumber, tomatoes, raspberries | Early spring |
| Pumpkins | Corn | Potatoes | Early summer |
| Radishes | Beans, beets, carrots, cucumbers, lettuce, peas, spinach, tomatoes | | Early spring |
| Squash | Radishes | Potatoes | Early summer |
| Tomatoes | Asparagus, basil, carrots, chive, garlic, onions, parsley | Cabbages, fennel, potatoes | Dependent on the variety |
| Turnips | Beans, peas | | Early spring |

**Watering Raised Beds**

When the soil inside the planting bed pulls away from the edges of the bed, it's time to water. The best time of day to water is in the late afternoon or early- to mid-morning. Avoid watering in midday, when the sun is hottest and water will quickly evaporate, or near sundown or at night, when too much moisture in the soil can cause mold and fungus to grow.

## Companion Planting

The old adage is true—some vegetables do actually get along "like peas and carrots." Some species of vegetables are natural partners that benefit from each other when planted close. On the other hand, some combinations are troublesome, and one plant will inhibit the growth of another. You can plant these antagonists in the same garden—even in the same raised garden bed—just don't place them side by side. Use the table on p. 34 to help you plan out your raised garden beds to ensure that your plants grow healthy, strong, and bear plentiful fruit.

## Start with Healthy Soil

The success or failure of any gardening effort generally lies beneath the surface. Soil is the support system for all plants—it provides a balanced meal of the nutrients that plants' roots need to grow deep and strong. If you plan to fill your raised beds with soil from your property, it's a good idea to have the soil tested first to assess its quality. Take a sample of your soil and submit it to a local agricultural extension service—a basic lab test will cost you between $15 and $25 and will give you detailed information about the nutrients available in your property's soil. Mixing soil from your property with compost, potting soil, or other additives is a smart and inexpensive way to improve its quality. After you've filled your beds with soil, add a three-inch layer of mulch to the top to lock in moisture and keep your good soil from blowing away in strong winds. Lawn clippings, wood, or bark chips, hay and straw, leaves, compost, and shredded newspaper all work well as mulch materials.

**Sprinklers with high**, arching spray patterns are afflicted by excess water evaporation, but if you choose a small, controllable sprinkler with a water pattern that stays low to the ground you can deliver water to your raised bed with minimal loss.

# How to Build a Raised Bed

**1 This basic but very sturdy** raised bed is made with 4 × 4 landscape timbers stacked with their ends staggered in classic log-cabin style. The corners are pinned together with 6" galvanized spikes (or, you can use timber screws). It is lined with landscape fabric and includes several weep holes in the bottom course for drainage. Consider adding a 2 × 8 ledge on the top row. Corner finials improve the appearance and provide hose guides to protect the plants in the bed.

**2 Create an outline** around your garden bed by tying mason's string to the stakes. Use a shovel to remove the grass inside the outline, then dig a 4"-wide trench for the first row of timbers around the perimeter. Lay the bottom course of timbers in the trenches. Where possible, add or remove soil as needed to bring the timbers to level—a level bed frame always looks better than a sloped one. If you do have a significant slope to address, terrace the beds.

**3 Add the second layer,** staggering the joints. Drill pilot holes at the corners and drive 6" galvanized spikes (or 6" to 8" timber screws) through the holes—use at least two per joint. Continue to build up layers in this fashion, until your bed reaches the desired height.

**4 Line the bed** with landscape fabric to contain the soil and help keep weeds out of the bed. Tack the fabric to the lower part of the top course with roofing nails. Some gardeners recommend drilling 1"-dia. weep holes in the bottom timber course at 2-ft. intervals. Fill with a blend of soil, peat moss, and fertilizer (if desired) to within 2 or 3" of the top.

# How to Build a Raised Bed from a Kit

**1 Raised garden bed kits** come in many styles. Some have modular plastic or composite panels that fit together with grooves or with hardware. Others feature wood panels and metal corner hardware. Most kits can be stacked to increase bed height.

**2 On a flat surface,** assemble the panels and corner brackets (or hinge brackets) using the included hardware. Follow the kit instructions, making sure all corners are square.

**3 Set the box down,** experimenting with exact positioning until you find just the spot and angle you like. Be sure to observe the sun over an entire day when choosing the sunniest spot you can for growing vegetables. Cut around the edges of the planting bed box with a square-nose spade, move the box, and then slice off the sod in the bed area.

**4 Set the bed box** onto the installation site and check it for level. Add or remove soil as needed until it is level. Stake the box to the ground with the provided hardware. Add additional box kits on top of or next to the first box. Follow the manufacturer's instructions for connecting the modular units. Line the bed or beds with landscape fabric and fill with soil to within 2" or so of the top.

5

# Container Gardening

**If you're short on yard space but have a sunny spot like** a balcony, stoop, porch, roof, or even windowsill, then you have the potential to plant a productive vegetable garden. Many plants flourish in small planters or other portable containers, and with a few well-managed containers, you can yield a sizable bounty for a couple or small family. In some ways, container gardening is easier than having a full-blown vegetable garden: There are fewer weeds (if any), pests are less problematic, and diseases are easier to avoid. You also need fewer tools and plants can easily be moved to accommodate temperature fluctuations and light/shade patterns. If you're a beginner gardener just wanting to try your hand at growing your own food, container gardening could be a great solution for you.

**If you've never tried gardening**, container gardening is a good way to start.

**Fresh soil**

Do not reuse soil if you're growing tomatoes or other plants that are susceptible to blight and fungus. After the growing season is concluded, collect the soil from sensitive plant containers and disperse it into hardy planting beds.

The key to successful container gardening is water. Because of their limited size, even the largest containers simply cannot hold the amount of water the plants need to thrive without watering once every day—extremely thirsty plants may even need to be watered more frequently than that. Vegetable plants are especially thirsty, but herbs and fruit trees or bushes need careful watering as well. Mature tomato plants may need as much as a gallon of water every day to grow those juicy, delicious fruits. If you bury your finger in the pot and you feel any dry soil—even 2" down—it's time to water.

Soil in container gardens is important too. A reliable rule of thumb is to use a 50/50 mix of potting soil to compost. Soil from your property typically won't hold water as well as potting soil on its own, so it's best not to use it in container gardens without adding a significant amount of organic fertilizer, which you can buy at the garden center or mix yourself. The following pages provide guidelines about the types of containers you can use and step-by-step instructions to help you build your own planter boxes.

## What to Grow

Most plants that grow well in your garden will also thrive in containers. Root vegetables are perhaps the only exception to this rule. Keep in mind that the larger the plant, the larger the container you'll need. Generally, the plant should not be more than twice the height of the pot or 1-1/2 times as wide. Use the guidelines below as a rough guide.

**Containers 4 to 6" deep:** Mustard greens, radishes, and spinach can all grow in shallow containers.

**Containers at least 8" deep:** Corn (container must be at least 21" wide, however, and house at least three plants to assure pollination), kale, lettuce.

**Containers at least 12" deep:** Beans, beets, brussel sprouts, cabbage (should also be pretty wide), carrots, chard, collards, kohlrabi, onion, peas, turnips, zucchini.

**Containers at least 16" deep:** Cucumber, eggplant, peppers.

**Containers at least 20" deep:** Broccoli, bok choy, Chinese cabbage.

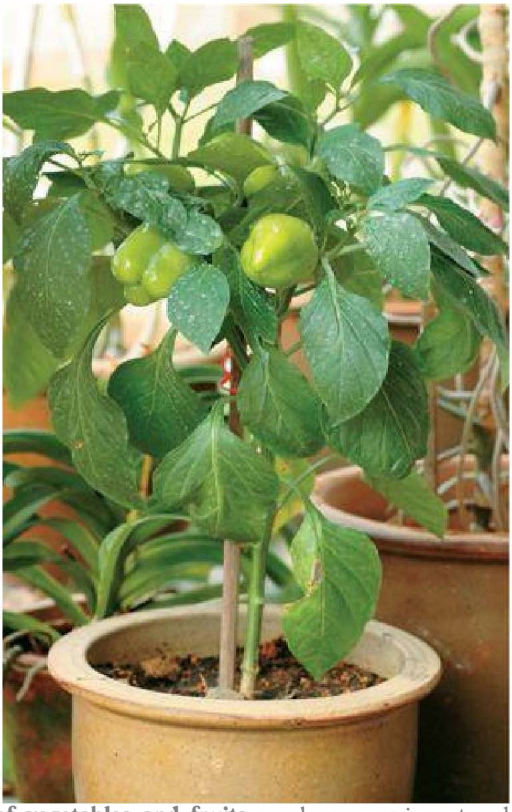
**More than 24" deep:** Squash, tomatoes.

## Container Types and Recommendations

As a container gardener, you'll quickly discover that the universe of usable containers is infinitely larger than the plain clay flowerpot. Essentially, any sturdy, watertight container will do. Large containers like wine barrels or old wash tubs and smaller containers like an ice cream pail or 5-gallon bucket can all be good for different kinds of plants. Large wooden troughs and DIY planter boxes can be customized to your garden (and are fun to make, too). When building your own planters, it's a good idea to line the inside with perforated polyethylene sheeting before adding potting soil to protect the wood from rot and to make it easier to empty out soil after a season.

Always make sure that the container you choose did not previously hold any kind of chemical and, if it does not already have them, drill drainage holes near the bottom of the container before filling with soil. If you'll be using large containers, it's usually a good idea to place them on a platform fitted with casters before filling them with potting soil.

Self-watering pots make container gardening less of a drain on your time. These containers are, essentially, a flowerpot set just above a reservoir of water. With this type of container, the soil above will wick up moisture from the reservoir as it needs it—keeping the soil consistently moist throughout and eliminating the possibility of over-watering. With a self-watering container, you may only need to add water every three to four days, and your plants will likely be less stressed. Ideally, your plants will therefore provide a more sizable crop at the end of the season.



**Many varieties of vegetables and fruits** can be grown in pots, planters, and other vessels—just make sure to select a container that is the right size for your plant and always add ample drainage holes if they're not already present.

**Spinach, leaf lettuce and a few shallots** co-exist in this self-watering planter. Self-watering containers have a water reservoir below to keep the soil in the pot moist. All you have to do is keep the reservoir full, and rainfall may even take care of this for you.

# Planter Boxes

Decorating a garden is much like decorating a room in your home—it's nice to have pieces that are adaptable enough that you can move them around occasionally and create a completely new look. After all, most of us can't buy new furniture every time we get tired of the way our living rooms look. And we can't build or buy new garden furnishings every time we want to rearrange the garden.

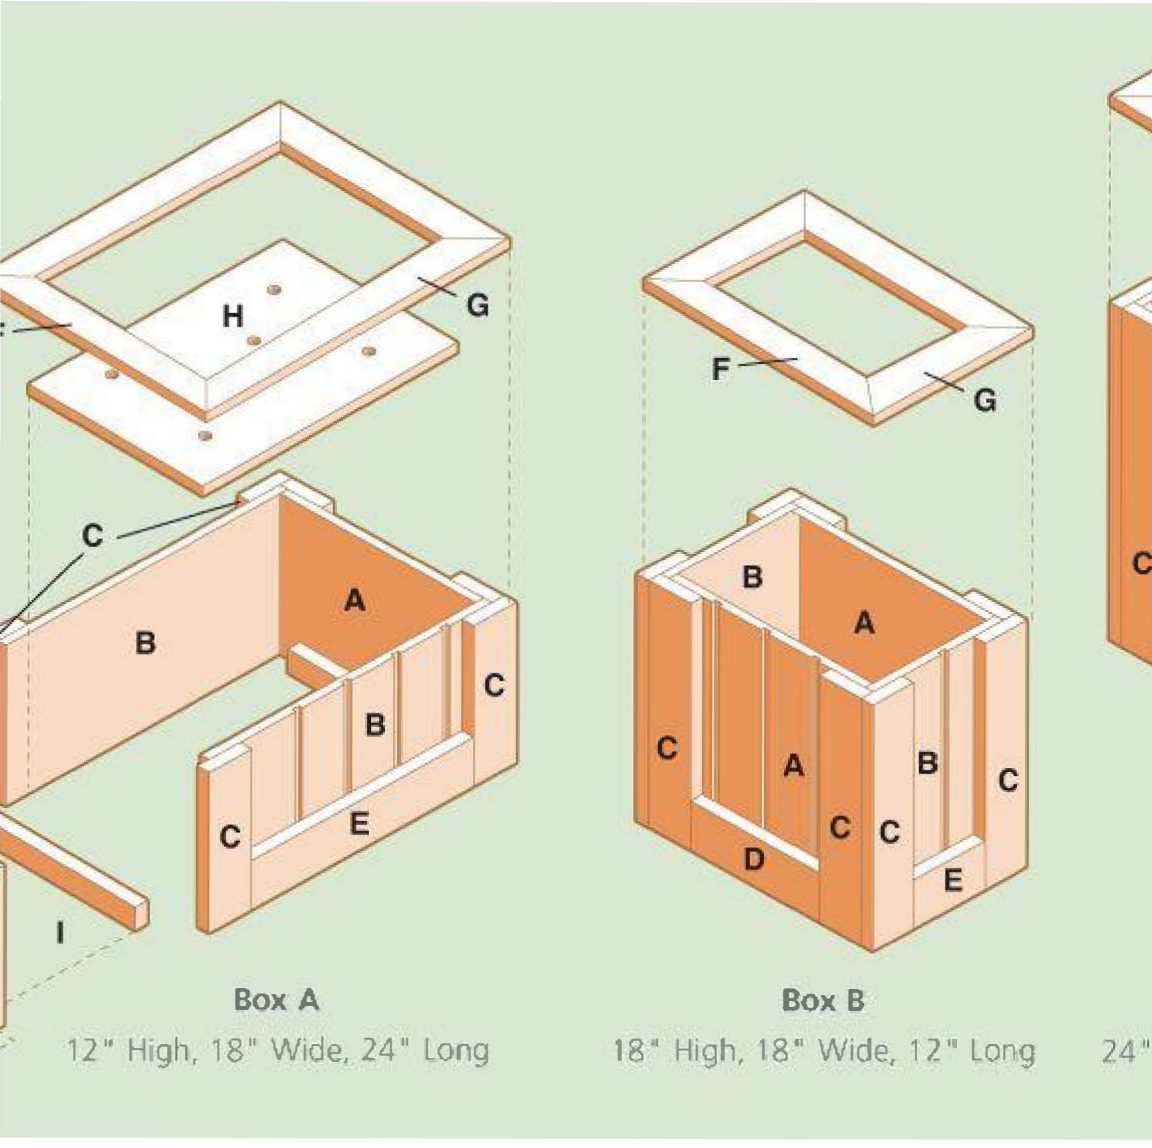
That's one of the reasons this trio of planter boxes works so well. In addition to being handsome—especially when flowers are bursting out of them—they're incredibly adaptable. You can follow these plans to build a terrific trio of planter boxes that will go well with each other and will complement most gardens, patios, and decks. Or you can tailor the plans to suit your needs. For instance, you may want three boxes that are exactly the same size. Or you might want to build several more and use them as a border that encloses a patio or frames a terraced area.

Whatever the dimensions of the boxes, the basic construction steps are the same. If you decide to alter the designs, take a little time to figure out the new dimensions and sketch plans. Then devise a new cutting list and do some planning so you can make efficient use of materials. To save cutting time, clamp together parts that are the same size and shape and cut them as a group (called gang cutting).

When your planter boxes have worn out their welcome in one spot, you can easily move them to another, perhaps with a fresh coat of stain, and add new plantings. You can even use the taller boxes to showcase outdoor relief sculptures—a kind of alfresco sculpture gallery.

**Whether you build** only one or all three, these handy cedar planters are small enough to move around your gardens and inside your greenhouse or garden shed.

## Building Planter Boxes



## CUTTING LIST

| t | Box A Dimension | Box B Dimension | Box C Dime |
|---|---|---|---|
| d panel | ⅝ × 15 × 11⅛" | ⅝ × 15 × 17⅛" | ⅝ × 15 × 23 |
| e panel | ⅝ × 22¼ × 11⅛" | ⅝ × 10¼ × 17⅛" | ⅝ × 10¼ × |
| rner trim | ⅞ × 3½ × 11⅛" | ⅞ × 3½ × 17⅛" | ⅞ × 3½ × 2 |
| tom trim | ⅞ × 3½ × 9¼" | ⅞ × 3½ × 9¼" | ⅞ × 3½ × 9 |
| tom trim | ⅞ × 3½ × 17" | ⅞ × 3½ × 5" | ⅞ × 3½ × 5 |
| ) cap | ⅞ × 1½ × 18" | ⅞ × 1½ × 18" | ⅞ × 1½ × 1 |
| ) cap | ⅞ × 1½ × 24" | ⅞ × 1½ × 12" | ⅞ × 1½ × 1 |
| tom panel | ¾ × 14½ × 19½" | ¾ × 14½ × 8½" | ¾ × 14½ × |
| at | ⅞ × 1½ × 12" | ⅞ × 1½ × 12" | ⅞ × 1½ × 1 |

eflect the actual size of dimension lumber.

## TOOLS AND MATERIALS

Tape measure
Circular saw
Straightedge
Drill
Finishing sander
Miter box and backsaw
(3) 8-ft. cedar 1 × 2s
(6) 8-ft. cedar 1 × 4s
4 × 8-ft. sheet of 5/8" T1-11 siding
2 × 4-ft. piece 3/4" CDX plywood
1-1/4" galvanized deck screws
1-5/8" galvanized deck screws
6d galvanized finish nails
Exterior wood stain
Paintbrush
Landscape fabric

# How to Build Planter Boxes

**1 Cut all the** wood parts to size according to the Cutting List on page 43. Use a circular saw and a straightedge cutting guide to rip siding panels (if you have access to a tablesaw, use that instead). You can make all three sizes, or any combination you choose.

**2 Assemble the box** frame. Place the end panel face down and butt it against a side panel. Mark the locations of several fasteners on the side panel. Drill counterbored 3/32" pilot holes in the side panel at the marked locations and fasten the side panel to the end panel with 1-5/8" deck screws. Fasten the opposite side panel the same way. Attach the other end panel with deck screws.

**3 Attach the corner** trim. Position one piece of corner trim flush to the corner edge and fasten to the panels with 1-5/8" galvanized deck screws driven into the trim from the inside of the box. Place the second piece of trim flush to the edge of the first piece, creating a square butt joint. Attach to the panel with 1-5/8" galvanized deck screws. For extra support, end nail the two trim pieces together at the corner with galvanized finish nails.

**4 Attach the bottom** trim. Fasten the bottom trim to the end and side panels, between the corner trim pieces and flush with the bottom of the box. Drive 1-1/4" deck screws through the panels from the inside to fasten the trim pieces to the box.

**5 Attach the cap** pieces. Cut 45° miters at both ends of one cap piece using a miter box and backsaw or a power miter saw. Tack this piece to the top end of the box, with the outside edges flush with the outer edges of the corner trim. Miter both ends of each piece and tack to the box to make a square corner with the previously installed piece. Once all caps are tacked in position and the miters are closed cleanly, attach the cap pieces using 6d galvanized finish nails.

**6 Install the cleats** to hold the box bottom in place. Screw to the inside of the end panels with 1-5/8" deck screws. If your planter is extremely tall, fasten the cleats higher on the panels so you won't need as much soil to fill the box. If doing so, add cleats on the side panels as well for extra support.

**7 Finish and install** the bottom. Cut the bottom panel to size from 3/4"-thick exterior-rated plywood. Drill several 1"-dia. drainage holes in the panel and set it onto the cleats. The bottom panel does not need to be fastened in place, but for extra strength, nail it to the cleats and box sides with galvanized finish nails.

**8 Finish the box** or boxes with wood sealer-preservative. When the finish has dried, line the planter box with landscape fabric, stapling it at the top of the box. Trim off fabric at least a couple of inches below the top of the box. Add a 2"-layer of gravel or stones, then fill with a 50/50 mix of potting soil and compost. **TIP:** Add wheels or casters to your planter boxes before filling them with soil. Be sure to use locking wheels or casters with brass or plastic housings.

## Building an Old-fashioned Strawberry Barrel

Container gardens aren't just for vegetables—fruit trees and berry bushes also thrive in a potted garden environment and can produce enough fruit for a family to enjoy throughout the summer. Strawberries, which typically grow in long rows or patches in the ground, can also be grown in a converted barrel. Two can be enough space to grow the equivalent of 25 feet of strawberry plants. For this project, make sure you choose everbearing strawberry varieties, and cut off runners for transplanting when they appear. Insulate your barrels with hay or straw during the winter, and you can enjoy a strawberry crop for several years. To keep your barrel going, start fresh every four or five years with new plants and new soil.

**A strawberry barrel** planter can grow the equivalent of 25 ft. of strawberry plants; choose everbearing varieties for best results.

## TOOLS & MATERIALS

Large, clean barrel (55-gallon plastic or wood)
Pry bar or jigsaw
3"-dia. hole saw
Drill
4"-dia. PVC Pipe
Window screen or hardware cloth
Gravel
Potting soil mix
Strawberry plants

# How to Build a Strawberry Barrel

**1 Prepare the barrel.** If your barrel has a lid or closed top, remove it with a pry bar. If your barrel does not have a lid, cut a large opening in the top with a jigsaw. Beginning about 1 ft. above the ground, use a hole saw to cut 3"-dia. planting holes around the barrel, about 10" apart. Stagger the holes diagonally in each row and space the rows about 10" apart. Leave at least 12" above the top row of holes. Flip the barrel over and drill about a half dozen 1/2"-dia. drainage holes in the bottom.

**2 Prepare the watering pipe.** Cut a section of 4"-dia. PVC pipe to fit inside the barrel from top to bottom. Punch or drill 3/4"-dia. holes in the pipe every 4 to 6", all the way around. Cut a section of window screen or hardware cloth to fit inside the bottom of the barrel and place it inside. Cover the screen with 2" of gravel or small rocks.

**3 Begin to fill** the barrel with soil. Have a friend hold the watering pipe in the center of the barrel and fill the pipe with coarse gravel. Then, begin to add soil to the bottom of the barrel, packing it firmly around the watering pipe in the bottom with a piece of scrap lumber. Add water to help the soil settle. Continuing adding soil until you reach the bottom of your first row of planting holes.

**4 Add soil and plants.** Carefully insert your strawberry plants into the holes, spreading the roots into a fan shape. Add soil on top of the roots and lightly water. Continue to add soil and plants, packing soil gently and watering after each planting, until you reach the top of the barrel. Do not cover the watering pipe. Plant additional strawberries on top of the barrel. Insert a hose into the watering pipe and run water for several minutes to give the barrel a good soaking.

6

# Building a Cold Frame

**An inexpensive foray into greenhouse gardening, a cold frame** is practical for starting plants six to eight weeks earlier in the growing season and for hardening off seedlings. Basically, a cold frame is a box set on the ground and topped with glass or plastic. Although mechanized models with thermostatically controlled atmospheres and sash that automatically open and close are available, you can easily build a basic cold frame yourself from materials you probably already have around the house.

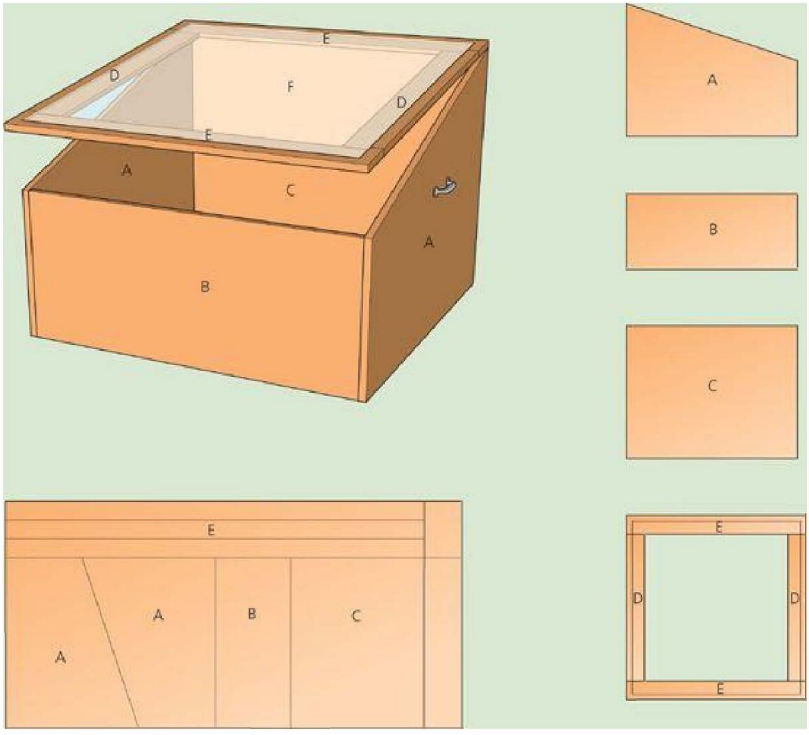
**Starting plants early** in a cold frame is a great way to get a head start on the growing season. A cold frame is also a great place for hardening off delicate seedlings to prepare them for transplanting.

The back of the frame should be about twice as tall as the front so the lid slopes to a favorable angle for capturing sunrays. Build the frame tall enough to accommodate the maximum height of the plants before they are removed. The frame can be made of brick, block, plastic, wood, or just about any material you have on hand. It should be built to keep drafts out and soil in.

If the frame is permanently sited, position it facing south to receive maximum light during winter and spring and to offer protection from wind. Partially burying it takes advantage of the insulation from the earth, but it also can cause water to collect and the direct soil contact will shorten the lifespan of the wood frame parts. Locating your frame near a wall, rock, or building adds additional insulation and protection from the elements. **TIP:** The ideal temperature inside is 65 to 75° F during the day and 55 to 65° at night. Keep an inexpensive thermometer in a shaded spot inside the frame for quick reference. A bright spring day can heat a cold frame to as warm as 100°, so prop up or remove the cover as necessary to prevent overheating. And remember, the more you vent, the more you should water. On cold nights, especially when frost is predicted, cover the box with burlap, old quilts, or leaves to keep it warm inside.

**A cold frame** should only be used during the early, cooler days of the growing season when delicate seedlings need that extra protection, and for late-season frost protection. Once the warmer weather arrives and the plants are established, remove and relocate the cold frame. Ongoing usage will overheat and kill the plants. And while the clear acrylic lid on this cold frame is desirable because it is safer to work with and use than glass, too much heat buildup can cause the acrylic to warp.

# Building a Cold Frame



## CUTTING LIST

| Key | Part | No. | Size | Material |
|---|---|---|---|---|
| A | Side | 2 | ¾ x 16/28 x 36" | Ext. Plywood |
| B | Front | 1 | ¾ x 16 x 36" | Ext. Plywood |
| C | Back | 1 | ¾ x 28 x 36" | Ext. Plywood |
| D | Lid frame | 2 | ¾ x 4 x 31" | Ext. Plywood |
| E | Lid frame | 2 | ¾ x 4 x 38" | Ext. Plywood |
| F | Cover | 1 | ⅛ x 37 x 38" | Plexiglas |

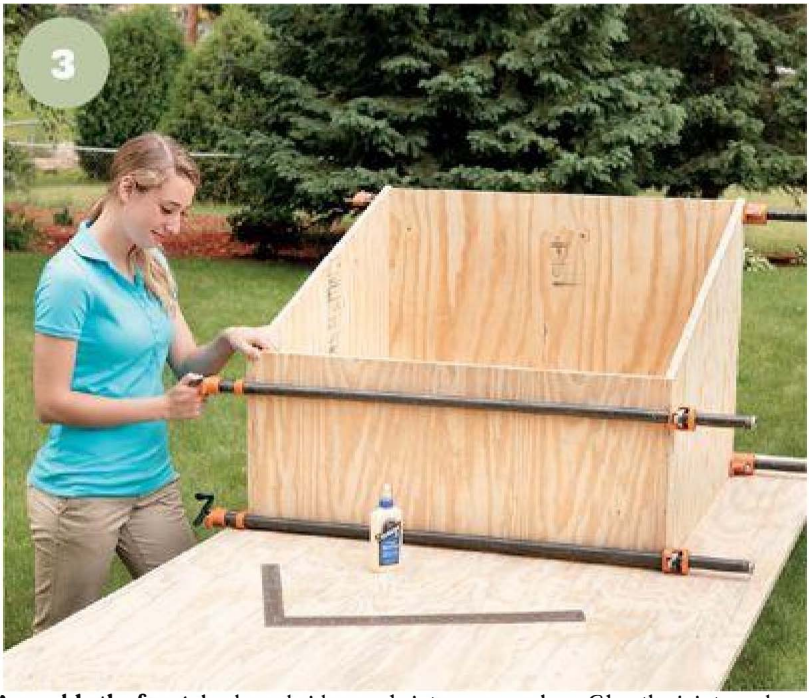
## TOOLS AND MATERIALS

(2) 3 × 3" butt hinges (ext.)
(2) 4" utility handles
(4) Corner L-brackets (3/4 × 2-1/2")
(1) 3/4" × 4 × 8 ft. Plywood (Ext.)
1/8 × 37 × 38" clear Plexiglas
Exterior caulk/adhesive
Exterior wood glue
Exterior paint
2" deck screws
#8 × 3/4" wood screws
Circular saw
Drill/driver
Pipe clamps
Straightedge cutting guide

# How to Build a Plywood Cold Frame

**1 Cut the parts.** This project, as dimensioned, is designed to be made entirely from a single 4 × 8 sheet of plywood. Start by cutting the plywood lengthwise to make a 36"-wide piece. **TIP:** Remove material in 4" wide strips and use the strips to make the lid frame parts and any other trim you may want to add.

**2 Trim the parts** to size with a circular saw or jigsaw and cutting guide. Mark the cutting lines first (See Diagram, p. 51).



**3 Assemble the front,** back, and side panels into a square box. Glue the joints and clamp them together with pipe or bar clamps. Adjust until the corners are square.

**4 Reinforce the joints** with 2" deck screws driven through countersunk pilot holes. Drive a screw every **4** to 6" along each joint.

**5 Make the lid frame.** Cut the 4"-wide strips of 3/4" plywood reserved from step 1 into frame parts. Assemble the frame parts into a square 38 × 39" frame. There are many ways to join the parts so they create a flat frame. Because the Plexiglas cover will give the lid some rigidity, simply gluing the joints and reinforcing with an L-bracket at each inside corner is adequate structurally.

**6 Paint the box** and the frame with exterior paint, preferably in an enamel finish. A darker color will hold more solar heat.

**7 Lay thick beads** of clear exterior adhesive/caulk onto the tops of the frames and then seat the Plexiglas cover into the adhesive. Clean up squeeze-out right away. Once the adhesive has set, attach the lid with butt hinges and attach the handles to the sides.

**8 Move the cold frame** to the site. Clear and level the ground where it will set. Some gardeners like to excavate the site slightly—see discussion on page 49.

7

# Starting & Transplanting Seedlings

**Add weeks to your garden's growing season by starting seeds** indoors, then transplanting them to the garden after the danger of frost is past. Seedlings are available for purchase at the garden center in the spring, of course, but starting your own at home presents a number of advantages:

**Seedlings need** a lot of water, sunlight, and warmth in their infancy. A kitchen window or greenhouse is an ideal growing environment for propagating plants.

**Using colored cups** as starter containers has the advantage of letting you color-code your plants so you can avoid any confusion. Beginning gardeners often have trouble distinguishing one pot from another when they are still seedlings. Here, the red cups clearly communicate "tomato."

- Buying seeds is less expensive than buying seedlings.
- You can cull out all but the strongest seedlings, which will hopefully result in stronger plants and a more bountiful crop.
- Garden centers sell seeds for a diverse and varied array of plants, but seedlings for only the most common species. Seed catalogs introduce an entirely new selection as well.
- You can be certain that unwanted pesticides have not been used on the plants in your garden, even in their infancy.

Start your seeds eight to ten weeks before you plan to transplant them into your garden. To get started, you'll need a few small containers, a suitable growing medium, and a bright spot for the seedlings to grow—either a sunny window that receives at least six hours of bright sunlight per day, a greenhouse, or a planting table in your home that's illuminated by artificial grow lights. If you're planning to raise your seedlings by artificial light, position one or two fluorescent lighting fixtures fitted with 40-watt, full-spectrum bulbs about six inches above the seedlings. Leave fluorescent lights on for 12 to 16 hours a day—many gardeners find it helpful to connect the fixture to a timer to ensure their plants receive adequate light each day.

**A 4-ft.,** two-bulb fluorescent light fixture that can be raised or lowered over a table is really all you need to start your vegetable plants indoors.

## Growing Mediums

If you plan to use your own garden soil or compost, prepare your seedling containers in the fall, before the ground gets too cold and wet.

Almost any small container can be used to grow seedlings. Just make sure the container you use is clean and hasn't had contact with any chemical that could be poisonous to plants. Also, remember to cut a drainage hole in the bottom of your container before filling it with soil. Drainage is very important to ensure that your plants are well ventilated. Excessively moist soil can result in mold or other diseases, as well. Good options for seedling containers include:

- Peat pots or pellets
- Fiber cubes
- Used plastic jugs
- Cans (any size)
- Used plastic tubs (i.e., sour cream,
- cottage cheese, or margarine containers)
- Used yogurt cups
- Egg cartons
- Small paper cups

Potting
Mix

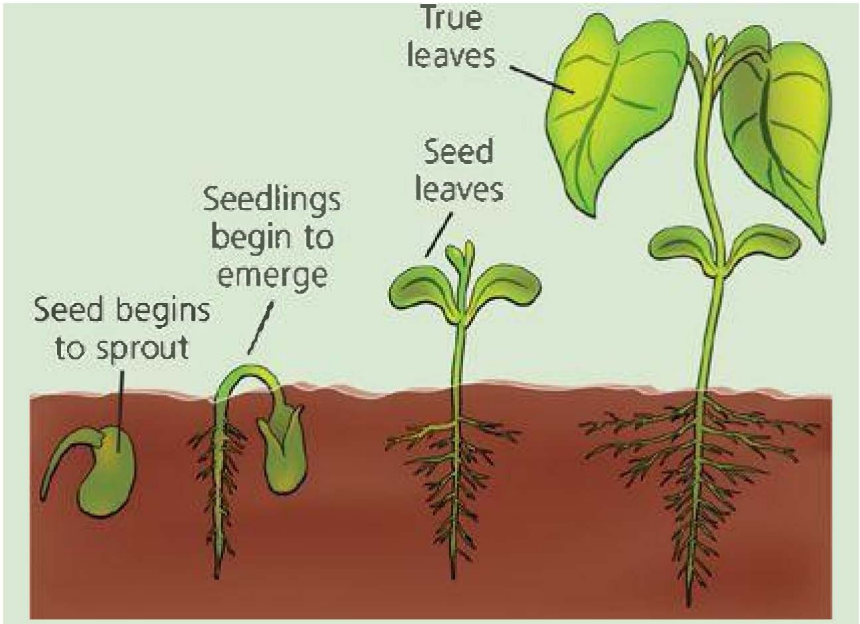
## Starting Seedlings

**1. Planting:** Sow three to four seeds in each container according to the instructions on the seed packet—as a general rule, large seeds should be buried and small seeds can be sprinkled on top of the soil. Label the container with the type of plant and the date your seeds were planted.

**2. Germination:** Water the seeds whenever the containers look dry. Until the seeds sprout, keep seedlings in a dark, warm space. Cover germinating seeds with plastic bags or plastic wrap. Open the plastic for a few hours every few days to let the soil breathe, then re-close.

**3. Sprouts:** When the seeds sprout, remove plastic covering and move them into direct light. Seedlings need lots of light to grow. Keep the soil medium moist but not soggy. Remember, multiple light waterings are better for seedlings than the occasional soaking.

**4. Culling:** When the true leaves appear (see illustration), cut off all but the strongest seedling in each container at soil level. Do not pull up the unwanted seedlings, as this may damage the roots of the seedling you're cultivating. You may also choose to fertilize every week or so as your seedlings grow.



**The four stages** in the growth of a seedling are illustrated above. Note that seed leaves and true leaves serve different purposes and will look different. When a plant has 4 to 8 true leaves, it is ready for transplanting.

## Hardening Off and Transplanting

When your seedlings have four to eight true leaves, they should be hardened off, then transplanted to the garden. Hardening off is the process of gradually introducing the plant to outdoor conditions so it is not shocked when you move it outside permanently. About two weeks before planting, place your seedlings outdoors for an hour the first day, and then gradually increase the time until your seedlings spend the whole day outside. Protect seedlings from wind and do not expose them to the midday sun for the first few days. Stop fertilizing seedlings during the last week. A cold frame is a great environment for hardening off seedlings. Seedlings can stay in a cold frame for two to three weeks, gradually getting used to the cooler air and chilly nights before they go out into the garden. Open the lid of the cold frame a little bit more each day.

Transplant your seedlings into the garden on a cloudy day or in late afternoon to avoid excessive drying from the sun. Remove seedlings gently from their containers, holding as much soil as possible around the roots (containers that are pressed from peat are not intended to be removed). Place each into a hole in your garden, spreading the roots carefully, then pack soil around the seedling to hold it straight and strong. Thoroughly soak all seedlings with a very gentle water spray after they've been planted. If you have a rain barrel or another source for untreated water, this is a perfect application for it: The chlorine in most municipal water can be harmful to delicate plants.

8

# Building a Greenhouse

**Utilizing a greenhouse is a great way to extend and diversify** your garden, enabling you to grow more food for a longer period of time—and perhaps even grow foods that wouldn't otherwise survive in your climate. A greenhouse can be a decorative and functional building that adds beauty to your property, or a quick and easy temporary structure that serves a purpose and then disappears. The wood-framed greenhouse in this project is somewhere between these two types. The sturdy wood construction will hold up for many seasons. The plastic sheeting covering will last one to five seasons, depending on the material you choose, and is easy to replace when it starts to degrade.

**A wood-frame** greenhouse with sheet-plastic cover is an inexpensive, semipermanent gardening structure that can be used as a potting area as well as a protective greenhouse.

The five-foot-high kneewalls in this design provide ample space for installing and working on a conventional-height potting table. For a door, this plan simply employs a sheet of weighted plastic that can be tied out of the way for entry and exit. If you plan to go in and out frequently, you can purchase a prefabricated greenhouse door from a garden center or greenhouse materials provider. To allow for ventilation in hot weather, we built a wood-frame vent cover that fits over one rafter bay and can be propped open easily.

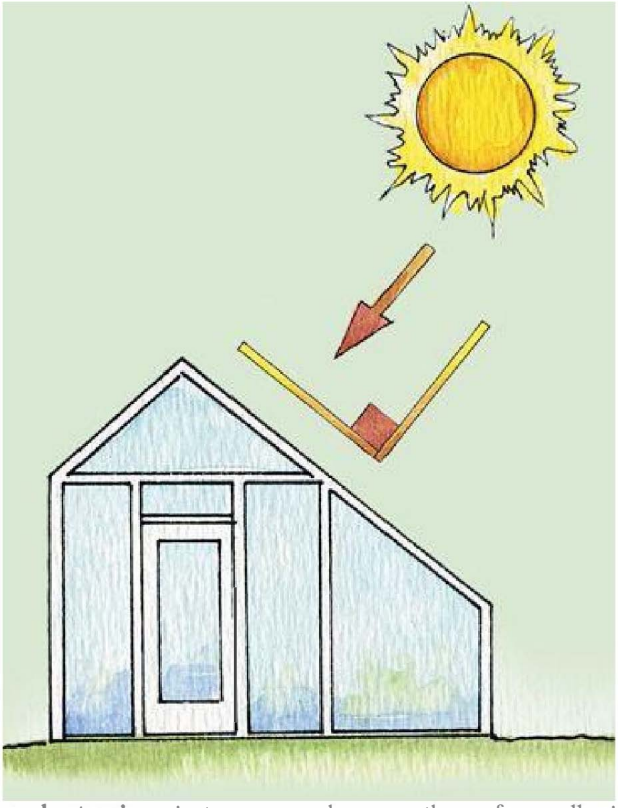
## Where to Site Your Greenhouse

When the first orangeries (early greenhouses) were built, heat was thought to be the most important element for successfully growing plants indoors. Most orangeries had solid roofs and walls with large windows. Once designers realized that light was more important than heat for plant growth, they began to build greenhouses from glass.

All plants need at least six (and preferably 12) hours of light a day year-round, so when choosing a site for a greenhouse, you need to consider a number of variables. Be sure that it is clear of shadows cast by trees, hedges, fences, your house, and other buildings. Don't forget that the shade cast by obstacles changes throughout the year. Take note of the sun's position at various times of the year: A site that receives full sun in the spring and summer can be shaded by nearby trees when the sun is low in winter. Winter shadows are longer than those cast by the high summer sun, and during winter, sunlight is particularly important for keeping the greenhouse warm. If you are not familiar with the year-round sunlight patterns on your property, you may have to do a little geometry to figure out where shadows will fall. Your latitude will also have a bearing on the amount of sunlight available; greenhouses at northern latitudes receive fewer hours of winter sunlight than those located farther south. You may have to supplement natural light with interior lighting.

To gain the most sun exposure, the greenhouse should be oriented so that its ridge runs east to west (see illustration), with the long sides facing north and south. A slightly southwest or southeast exposure is also acceptable, but avoid a northern exposure if you're planning an attached greenhouse; only shade-lovers will grow there.

**The ideal greenhouse** location is well away from trees but protected from prevailing winds, usually by another structure, a fence or a wall.



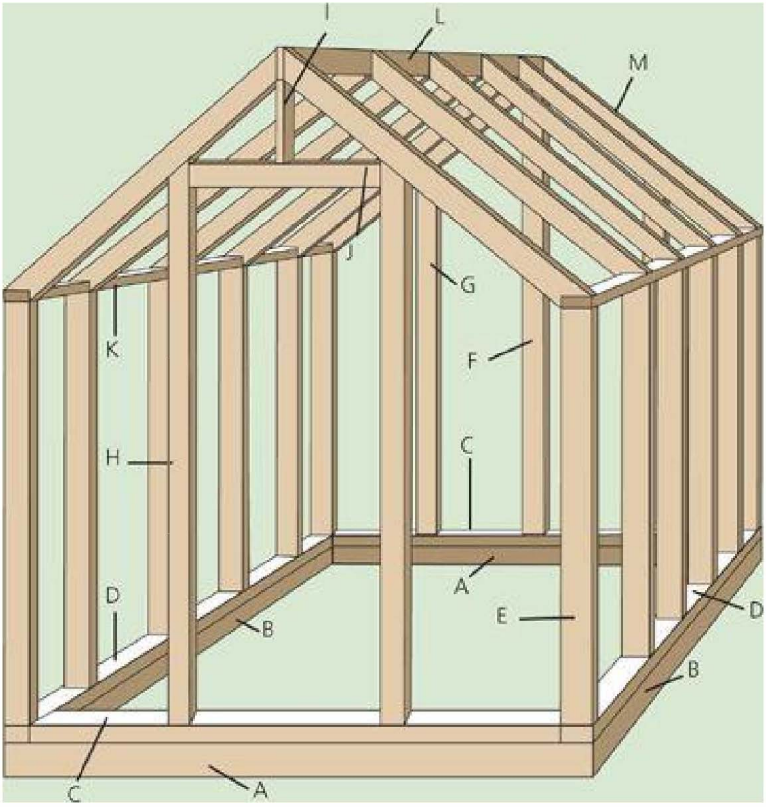
**For maximum heat gain,** orient your greenhouse so the roof or wall with the most surface area is as close to perpendicular to the sunrays as it can be.

# Building a Greenhouse

## CUTTING LIST

| Key | No. | Part | Dimension | Material |
|---|---|---|---|---|
| A | 2 | Base ends | 3½ x 3½ x 96" | 4 x 4 landscape timber |
| B | 2 | Base sides | 3½ x 3½ x 113" | 4 x 4 landscape timber |
| C | 2 | Sole plates end | 1½ x 3½ x 89" | 2 x 4 pressure treated |
| D | 2 | Sole plates side | 1½ x 3½ x 120" | 2 x 4 pressure treated |
| E | 12 | Wall studs side | 1½ x 3½ x 57" | 2 x 4 |
| F | 1 | Ridge support | 1½ x 3½ x 91" | 2 x 4 |
| G | 2 | Back studs | 1½ x 3½ x 76" * | 2 x 4 |
| H | 2 | Door frame sides | 1½ x 3½ x 81" * | 2 x 4 |
| I | 1 | Cripple stud | 1½ x 3½ x 16" | 2 x 4 |
| J | 1 | Door header | 1½ x 3½ x 32" | 2 x 4 |
| K | 2 | Kneewall caps | 1½ x 3½ x 120" | 2 x 4 |
| L | 1 | Ridge pole | 1½ x 3½ x 120" | 2 x 4 |
| M | 12 | Rafters | 1½ x 3½ x 60" * | 2 x 4 |

*Approximate dimension; take actual length and angle measurements on structure before cutting.



## TOOLS & MATERIALS

(1) 20 × 50-ft. roll 4 or 6-mil polyethylene sheeting or greenhouse fabric, tack strips
(12) 24"-long pieces of No. 3 rebar
(4) 16-ft. pressure-treated 2 × 4
(2) exterior-rated butt hinges
(1) screw-eye latch
(8) 8" timber screws
Reciprocating saw
Level
Carpenter's square
Drill with a nut driver bit
Eye and ear protection
Metal cutoff saw
Maul or sledgehammer
Speed square

3" deck screws
Exterior panel adhesive
Caulk gun
Hammer
Jigsaw or handsaw
Miter saw
Circular saw
Utility knife
Pneumatic nailer
Scissors
Scrap 2×4
Pencil

# How to Build a Gabled Greenhouse

**1 Prepare the installation** area so it is flat and well drained; then cut the base timbers (4 × 4 landscape timbers) to length. Arrange the timbers so they are flat and level and create a rectangle with square corners. Drive a pair of 8" timber screws at each corner, using a drill/driver with a nut-driver bit.

**2 Cut 12 pieces** of No. 3 rebar (find it in the concrete supplies section of any building center) to 24" in length to use as spikes for securing the timbers to the ground. A metal cutoff saw or a reciprocating saw with a metal cutting blade can be used to make the cuts. Drill a 3/8" guide hole through each timber near each end and in the middle. Drive a rebar spike at each hole with a maul or sledgehammer until the top is flush with the wood.

**3 Cut the plates** and studs for the two side walls (called kneewalls). Arrange the parts on a flat surface and assemble the walls by driving three 3" deck screws through the cap and base plates and into the ends of the studs. Make both kneewalls.

**4 Set the base plate** of each kneewall on the timber base and attach the walls by driving 3" deck screws down through the base plates and into the timbers. For extra holding power, you can apply exterior panel adhesive to the undersides of the plates, but only if you don't plan to relocate the structure later.

**5 Cut the ridge** support post to length and attach it to the center of one end base plate, forming a T. Cut another post the same length for the front (this will be a temporary post) and attach it to a plate. Fasten both plates to front and back end timbers.

**6 Set the ridge** pole on top of the posts and check that it is level. Also check that the posts are level and plumb. Attach a 2 × 4 brace to the outer studs of the kneewalls and to the posts to hold them in square relationship. Double-check the pole and posts with the level.

**7 Cut a 2 × 4** to about 66" to use as a rafter template. Hold the 2 × 4 against the end of the ridge pole and the top outside corner of a kneewall. Trace along the face of the ridge and the top plate of the wall to mark cutting lines. Cut the rafter and use it as a template for the other rafters on that side of the roof. Create a separate template for the other side of the roof.

**8 Mark cutting lines** for the rafters using the templates, and cut them all. You'll need to use a jigsaw or handsaw to make the bird's mouth cuts on the rafter ends that rest on the kneewall.

**9 Attach the rafters** to the ridge pole and the kneewalls with deck screws driven through pilot holes. Try to make the rafters align with the kneewall studs.

**10 Mark the positions** for the remaining end wall studs on the base plate. At each location, hold a 2 × 4 on end on the base plate and make it level and plumb. Trace a cutting line at the top of the 2 × 4 where it meets the rafter. Cut the studs and install them by driving screws toenail-style.

**11 Measure up 78"** (or less if you want a shorter door) from the sole plate in the door opening and mark a cutting line on the temporary ridge post. Make a square cut along the line with a circular saw or cordless trim saw (inset). Then cut the door header to fit between the vertical door frame members. Screw the header to the cut end of the ridge post and drive screws through the frame members and into the header.

**12 Begin covering the** greenhouse with your choice of cover material. (We used 6-mil polyethylene sheeting.) Start at the ends. Cut the sheeting to size and then fasten it by attaching screen retainer strips to wood surfaces at the edges of the area being covered. Tack the sheeting first at the top, then at the sides and finally at the bottom. After the strips are installed (use wire brads), trim the sheeting along the edges of the strips with a utility knife.

**13 Attach the sheeting** to the outside edge of the base plate on one side. Roll sheeting over the roof and down the other side. Draw it taut and cut it slightly overlong with scissors. Attach retainer strips to the other base plate and then to the outside edges of the corner studs.

**14 Make and hang** a door. We simply cut a piece of sheet plastic a little bigger than the opening (32") and hung it with retainer strips from the header. Attach a piece of 2 × 4 to the bottom of the door for weight.

**15** ***Option:*** **Make a vent** window. First, cut a hole in the roof in one rafter bay and tack the cut edges of the plastic to the faces (not the edges) of the rafters, ridge pole, and wall cap. Then build a frame from 1 × 2 stock that will span from the ridge to the top of the kneewall and extend a couple of inches past the rafters at the side of the opening. Clad the frame with plastic sheeting and attach it to the ridge pole with butt hinges. Install a screw-eye latch to secure it at the bottom. Make and attach props if you wish.

9

# Building a Hoophouse

**The hoophouse is a popular garden structure for two main** reasons: It is cheap to build and easy to build. In many agricultural areas you will see hoophouses snaking across vast fields of seedlings, protecting the delicate plants at their most vulnerable stages. Because they are portable and easy to disassemble, they can be removed when the plants are established and less vulnerable.

**A hoophouse** is a temporary agricultural structure designed to be low-cost and portable. Also called Quonset houses and tunnel houses, hoophouses provide shelter and shade

(depending on the film you use) and protection from wind and the elements. They will boost heat during the day, but are less efficient than paneled greenhouses for extending the growing season.

While hoophouses are not intended as inexpensive substitutes for real greenhouses, they do serve an important agricultural purpose. And building your own is a fun project that the whole family can enjoy.

The hoophouse shown here is essentially a Quonset-style frame of bent 3/4" PVC tubing draped with sheet plastic. Each semicircular frame is actually made from two 10-ft. lengths of tubing that fit into a plastic fitting at the apex of the curve. PVC tubes tend to stay together simply by friction-fitting into the fittings, so you don't normally need to solvent glue the connections (this is important to the easy-to-disassemble and store feature). If you experience problems with the frame connections separating, try cutting 4" to 6"-long pieces of 1/2" (outside diameter) PVC tubing and inserting them into the tubes and fittings like splines. This will stiffen the connections.

**Hoophouse frames** can be made from wood instead of PVC plastic. Wood allows you to attach plastic sheeting with retainer strips and staples.

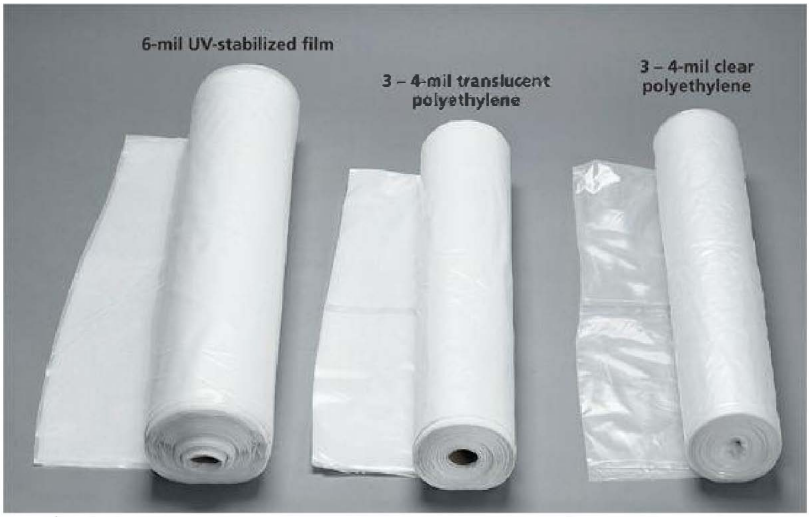
## Building & Siting a Hoophouse

The fact that a hoophouse is a temporary structure doesn't give you license to skimp on the construction. When you consider how light the parts are and how many properties sheet plastic shares with boat sails, the importance of securely anchoring your hoophouse becomes obvious. Use long stakes (at least 24") to anchor the tubular frames, and make sure you have plenty of excess sheeting at the sides of the hoophouse so the cover can be held down with ballast. Creating pockets at the ends of the sheeting and inserting scrap lumber is the ballasting technique shown here, but it is also common (especially when building in a field) to weigh down the sheeting by burying the ends in dirt. Only attach the sheeting at the ends of the tubular frame, and where possible, orient the structure so the prevailing winds won't blow through the tunnel.

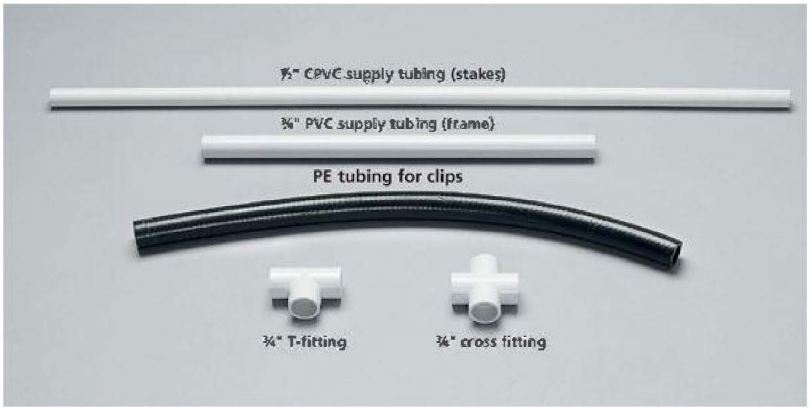
**Building a Hoophouse**

- Space frame hoops about 3 ft. apart.
- Leave ridge members a fraction of an inch (not more than 1/4") shorter than the span, which will cause the structure to be slightly shorter on top than at the base. This helps stabilize the structure.
- Orient the structure so the wall faces into the prevailing wind rather than the end openings.
- If you are using long-lasting greenhouse fabric for the cover, protect the investment by spray-painting the frame hoops with primer so there is no plastic-to-plastic contact.
- Because hoophouses are temporary structures that are designed to be disassembled or moved regularly, you do not need to include a base.
- The 3/4" PVC pipes used to make the hoop frames are sold in 10 ft. lengths. Two pipes fitted into a tee or cross fitting at the top will result in legs that are 10 ft. apart at the base and a ridge that is roughly 7 ft. tall.
- Clip the hoophouse covers to the end frames. Clips fastened at the intermediate hoops will either fly off or tear the plastic cover in windy conditions.

**Row tunnels are** often used in vegetable gardens to protect sensitive plants in the spring and fall. Plastic or fabric sheeting is draped over a short wire or plastic framework to protect plants at night. During the heat of the day, the sheeting can be drawn back to allow plants direct sunlight.

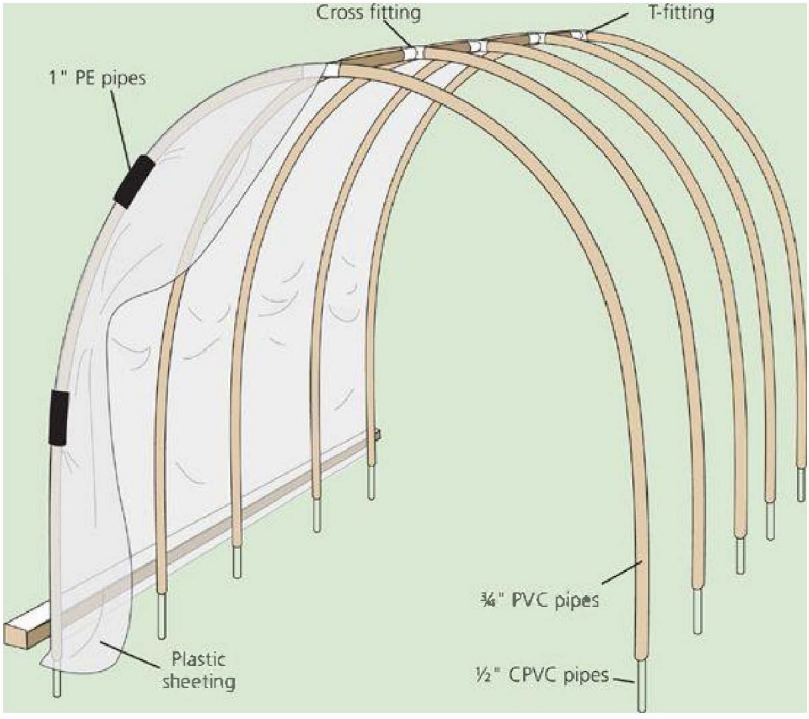


**Sheet plastic is** an inexpensive material for creating a greenhouse. Obviously, it is less durable than polycarbonate, fiberglass, or glass panels. But UV-stabilized films at least 6-mil thick can be rated to withstand four years or more of exposure. Inexpensive polyethylene sheeting (the kind you find at hardware stores) will hold up for a year or two, but it becomes brittle when exposed to sunlight. Some greenhouse builders prefer to use clear plastic sheeting to maximize the sunlight penetration, but the cloudiness of translucent poly makes it effective for diffusing light and preventing overheating. For the highest quality film coverings, look for film rated for greenhouse and agricultural use.



Plastic tubing and fittings used to build this hoophouse include: Light duty 3/4" PVC tubing for the frame (do not use CPVC—it is too rigid and won't bend properly); 1/2" CPVC supply tubing for the frame stakes (rigidity is good here); Polyethylene (PE) tubing for the cover clips; T-fittings and cross fittings to join the frame members.

# Building a Hoophouse

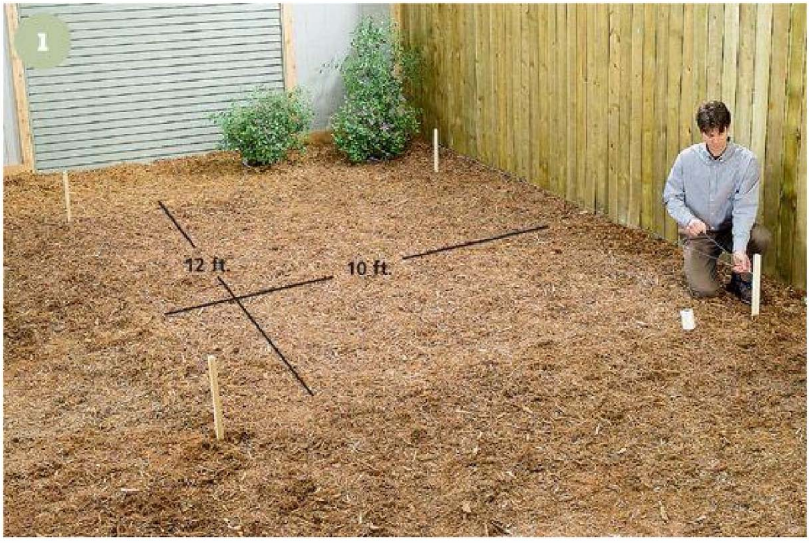


## TOOLS AND MATERIALS

(for 10-ft. wide × 15-ft. long project seen here)

(12) 3/4" × 10 ft. PVC pipes
(3) 1/2" × 10 ft. CPVC pipes
(1) 1" × 10 ft. PE pipe (black)
(3) 3/4" PVC cross fittings
(2) 3/4" PVC T-fittings
20 × 16 ft. clear or translucent plastic sheeting
(4) 12-ft. pressure-treated 2 × 4
Stakes
Mason's string
Tape measure
Circular saw
Painters' tape
Mallet
Maul
Stapler
2-1/2" deck screws
Drill

# How to Build a Hoophouse



**1 Lay out the** installation area using stakes and mason's string. Strive for square corners, but keep in mind that these are relatively forgiving structures, so you can miss by a little bit and probably won't be able to notice.

**2 Cut a 30"-long stake** from 1/2" CPVC supply tubing for each leg of each hoop frame. Measure out from the corners of the layout and attach a piece of high-visibility tape on the string at 3-ft. intervals; then drive a stake at each location. When the stake is fully driven, 10" should be above ground and 20" below.

3

**3 Join the two legs** for each frame hoop with a fitting. Use a tee fitting for the end hoop frames and a cross fitting for the intermediate hoop frames. No priming or solvent gluing is necessary. (The friction-fit should be sufficient, but it helps if you tap on the end of the fitting with a mallet to seat it.)

**4 Slip the open end** of one hoop-frame leg over a corner stake so the pipe is flush against the ground. Then bend the pipes so you can fit the other leg end over the stake at the opposite corner. If you experience problems with the pipes pulling out of the top fitting, simply tape the joints temporarily until the structure frame is completed.

**5 Continue adding hoop frames** until you reach the other end of the structure. Wait until all the hoop frames are in place before you begin installing the ridge poles. Make sure the cross fittings on the intermediate hoop frames are aligned correctly to accept the ridge poles.

**6 Add the ridge-pole** sections between the hoop frames. Pound on the end of each new section as you install it to seat it fully into the fitting. Install all of the poles.

**7 Cut four pieces** of pressure-treated 2 × 4 to the length of the hoophouse (12 ft. as shown). Cut the roof cover material to size. (We used 6-mil polyethylene sheeting.) It should be several inches longer than is necessary in each direction. Tack the cover material at one end of the 2 × 4 and then continue tacking it as you work your way toward the end. Make sure the material stays taut and crease-free as you go.

**8 Lay a second 2 × 4** the same length as the first over the tacked plastic so the ends and edges of the 2 × 4s are flush. Drive a 2-1/2" deck screw through the top 2 × 4 and into the lower one every 24" or so, sandwiching the cover material between the boards. Lay the assembly next to one edge of the hoophouse and pull the free end of the material over the tops of the frames.

**9 On the other side** of the structure, extend the cover material all the way down so it is taut and then position another 2 × 4 underneath the fabric where it meets the ground. Staple the plastic and then sandwich it with a final 2 × 4.

**10 Make clips** to secure the roof cover material from a 12"-long section of hose or soft tubing. Here, 1"-dia., thin-walled PE supply tubing is slit longitudinally and then slipped over the material to clip it to the end frames. Use at least six clips per end. Do not clip at the intermediate hoop frames.

**11** ***Option:*** Make doors by clipping a piece of cover material to each end. (It's best to do this before attaching the main cover.) Then cut a slit down the center of the end material. You can tie or tape the door material to the sides when you want it open and weigh down the pieces with a board or brick to keep the door shut. This solution is low-tech but effective.

10

# Preserving Your Bounty

**Preserving garden produce does not need to be an overwhelming** task, but it is important to think through your strategy before you get started. To understand how to preserve food, it's important first to understand why fresh fruits and vegetables spoil and decay. There are two main culprits: First, external agents, such as bacteria and mold, break down and consume fresh food. Second, naturally occurring enzymes—the very same ones that cause fruits and veggies to ripen—are also responsible for their decay. Canning, freezing, drying, and cold storage (along with salt-curing/smoking, and making fruit preserves) are all ways to slow down or halt these processes while retaining (to varying degrees) nutrition and taste.

**Canning is one** of the most popular forms of food preservation. The process is reliable and can be applied to a wide variety of vegetables.

**Drying Produce**

An electric food dehydrator is a fast, effective tool for drying fruit and vegetables. Because the produce is dried quickly in a closed environment, the process is very sanitary and yields consistent, predictable results.

Each method for preserving food has its strengths and weaknesses. It's important to weigh these carefully and decide which preservation method is the best fit for your garden's needs and your lifestyle.

## Choosing the Best Preservation Method

| Produce | Canning (See page 82) | Freezing (See page 81) | Dehydration (See page 84) | Live Storage (See page 92) |
|---|---|---|---|---|
| Apples | ✔ | | ✔ | ✔ |
| Asparagus | ✔ | ✔ | | |
| Beans (green) | ✔ | ✔ | | |
| Beans (lima) | ✔ | ✔ | ✔ | |
| Beets | ✔ | | | ✔ |
| Broccoli | | ✔ | ✔ | |
| Brussel Sprouts | | | ✔ | ✔ |
| Cabbage | | | | ✔ |
| Carrots | ✔ | ✔ | | ✔ |
| Cauliflower | | ✔ | | |
| Celery | | | | ✔ |
| Cherries | ✔ | | ✔ | |
| Corn | ✔ | ✔ | | |
| Cucumbers | ✔ (with pickling) | | | |
| Onions | | | | ✔ |

| Squash (winter) | ✔ | | | ✔ |
| Strawberries | | ✔ | ✔ | |
| Tomatoes | ✔ | ✔ | ✔ | |

**Canning.** Canning changes the taste of foods and results in some vitamin loss, but is versatile and can be used to preserve many different kinds of foods for lengthy periods of time.

**Cellaring.** Live storage preserves produce with minimal effect on taste or nutritional value, but it only makes sense for a few foodstuffs. The fruits and vegetables that can be cellared for limited periods of time require a storage environment that must be carefully regulated.

**Freezing and drying.** Freezing and drying both retain a high percentage of vitamins and have a minimum effect on flavor, but only certain foods can be preserved with these methods and careful preparation and regulation is extremely important. Freezing can damage the cellular structure of fruits and vegetables, causing an unpleasant mushiness that makes them suitable only for dices and purees. Drying also changes the nature of fruits and vegetables; for example, drying fruits causes the caloric value to double or triple as the starches convert to sugars during the process.

## Preservation by Freezing

Freezing is the best way to preserve delicate vegetables. It's also a quick process that is perfectly suited to smaller batches of food. In this process, foods should be blanched to stabilize nutrients and texture, cooled to preserve color, packaged in an airtight container, and frozen as quickly as possible. Frozen food, if properly packaged and contained within a temperature-consistent frozen environment, can be preserved for as long as a year. Of course, the longer you wait to eat your food, the more it will break down, which results in a loss of taste and freshness. Food can also absorb ambient flavors in the freezer environment, negatively affecting the taste.

**Freezer Tip**

Fill empty food containers, such as old milk jugs, with water and place them in the freezer around your frozen foods. With a freezer full of these homemade “ice packs,” your freezer will stay colder much longer in the event of a power outage and the appliance will work at maximum efficiency, consuming less energy.

Generally, the colder you keep your freezer, the longer your frozen food will stay tasting fresh. For best results, use a chest freezer instead of the little box above your refrigerator. Although chest freezers are an investment, they maintain colder temperatures more consistently than your refrigerator's freezer. The ideal temperature for your chest freezer is –5°F, and it should be no warmer than 0°. Even a few degrees above zero will cut the freezer life of your food in half.

## Preservation by Home Canning

Canning is a traditional method for preserving produce. It is not difficult to master, but it's important to pace yourself. Try not to plan more than one canning project a day to keep the work manageable and enjoyable. Also, make sure you are familiar with how to use your canning equipment safely, and that you have a reliable recipe to reference for each food you plan to can. Every fruit and vegetable has a different acidity and requires slightly different accommodations in the canning process.

To get started with canning, there are two main tools to become familiar with: a water bath canner and a pressure canner. Foods with high acidity, such as fruits (including tomatoes), can be canned in a boiling water bath. Less acidic foods, including most vegetables, and any combination of high- and low-acidity foods must be processed using a pressure canner. Water bath and pressure canners are NOT interchangeable, largely because they reach vastly different temperatures during their processes. Always make sure the canner you use is appropriate for the produce you're preserving and follow your canning recipe exactly.

**Beware of Botulism**

Home canning is perfectly safe if all instructions are followed exactly. However, if canning procedures are not followed, harmful bacteria can fester while your produce sits in your pantry waiting to be used. The best known of these bacteria is *clostridium botulinum*, which produces a potent toxin that is odorless, colorless, and fatal to humans in small amounts. Cases of botulism poisoning are rare, but to avoid this toxic substance, it's important to always follow the home canning recipe and procedures exactly. And if in doubt, throw it out.

Other tools you'll need include canning jars, measuring cups, a long-handled spoon, a funnel, a jar lifter, and cooking pots. Canning jars typically have two-piece metal lids: The metal band can be reused whereas the disc part of the lid cannot form an adequate seal more than once, and should be discarded after one use. Always inspect jars carefully before beginning: Check for nicks on the rim or cracks anywhere in the jar. Discard or repurpose any imperfect jars as they will not be able to form an adequate seal.

**Make sure you understand** how to use your home canning equipment before you get started. Take time to read through the manual that comes with your canner, and make sure you use the right type of home canner for the fruit or vegetable you're planning to preserve. A pressure canner and sealable canning jars with two-piece lids are shown here.

## The Home Canning Process

**1. Wash and heat the jars.** Immerse jars in simmering water for at least 10 minutes or steam them for 15 minutes. Heat jar lids (just the disc part) in a small saucepan of water for at least 10 minutes. Keep lids hot, removing one at a time as needed.
**2. Pack food in the jars.** Different packing methods are used for different types of produce. In cold packing, raw food is placed in a hot jar and then hot liquid is poured over the food to fill the jar. In hot packing, foods are precooked and poured into a hot jar immediately after removing them from the heat source.
**3. Watch your headspace.** Headspace is the amount of space between the rim of the jar and the top of the food and is very important to making sure that your canning jars seal correctly. Always follow your recipe's directions—generally it's best to leave about 1" of headspace for low-acid foods, 1/2" for acidic foods, and 1/4" for pickles, relishes, jellies, and juices.
**4. Remove air bubbles.** Insert a nonmetal spatula or chopstick and agitate the food to remove all air bubbles.
**5. Place the lid.** Clean the jar rim, then set a hot disc on the jar rim and screw on the band until you meet the initial point of resistance and no further.
**6. Heat.** Place jars on the rack in the water bath or pressure canner and process immediately. Follow the directions for your canner.
**7. Cool.** Allow the jars to cool slowly after processing—cooling too quickly can cause breakage. Typically, jars should cool along with the water they're submerged in, but follow the directions for your canner. Do not tighten the lids unless they are very loose. As the jars cool, you'll hear them "pop" when they are properly sealed. If the jar does not seal, refrigerate and eat within the next couple days.
**8. Clean and label.** After cooling and confirming the jar's seal, wash the outside of the jar and label with the content and date.

**9. Store.** Store in a cool, dark cupboard or pantry. If a jar loses its seal during storage (i.e., if the metal disc does not pop when you remove it), the food inside is not safe to eat. Dump it on the compost bin and try a different jar.

## Canned Food Safety Quiz

Ask yourself the following ten questions to determine if your home-canned food is safe to eat:

1. Is the food in the jar covered with liquid and fully packed?
2. Has proper headspace been maintained?
3. Is the food free from moving air bubbles?
4. Does the jar have a tight seal?
5. Is the jar free from seepage and oozing from under the lid?
6. Has the food maintained a uniform color?
7. Is the liquid clear (not cloudy) and free of sediment?
8. Did the jar open with a clear "pop" or "hiss" and without any liquid spurts?
9. After opening, was the food free of any unusual odors?
10. Is the food and underside of the lid free of any cottonlike growths?
